A. Yes, we had another job that cost us a lot of inconvenience, and that was making bolts or headers. We used No. 13 bolts to tie the different of resistance together. The bolts could not be bought at that time, 13 inches long, so we had to make it from a three-eighths iron rod. And it was a very long job, threading a round the steel, and not very successful all the time, so when we got this welder made, we conceived the idea of buying seven-eighths bolts and cutting the heads off and putting them on this machine to butt weld them, and we did it successfully.

Q. 20. Do you remember any tests made of butt welds to ascertain strength?

A. Yes, sir. When we had these made, we told our blacksmith at that time what we were going to do, and he was very skeptical; he said it could not be done. So we told him how we were going to do it, and he was on the job to see us do it, and he made the test of its strength; he put it in a vise himself and bent it back and forth,

until it broke, and it broke, as I remember it, half an inch away from the weld.

Q. 21. Was this machine used to weld any other things?

A. Yes, sir. Another thing we did at our work was to make pressed ribbon resistance, we called it P. R., as it was named at that time. After we had this machine going, doing butt welding, Mr. Smith conceived the idea to spot weld those ribbons, and we did that very successfully for some time. In fact, we continued to do it until we began to discontinue the use of P. R. resistance for a different type of resistance.

Q. 22. Did that spot type of welding go into commercial use?

A. Yes, sir.

Q. 23. When did it first go into commercial use?

A. Immediately after we made the weld.

Q. 24. When was that?

A. That was in 1905.

Q. 25. Will you state whether it was the early or latter part of the year 1905?

A. I would say we had the machine finished, built, before Mr. Smith had been with us six months.

Q. 26. When did he come there?

A. In January, 1905.

Q. 27. Can you produce an illustrative sample of this spot welding that was done?

A. Yes, I can (producing).

Q. 28. Is this a fair illustration of the spot welding that was done on the Smith machine?

A. I would say it was a far nicer looking job from a mechanical standpoint.

X-Q. 29. When was this made?

A. That was done this morning.

Q. 30. And this is the kind of work that went into commercial use, as you stated?

A. Yes, sir, that is the exact size of the ribbon we used, and still continue to use it for other purposes in our work.

Q. 31. What was the resistance?

A. The resistance used in starting that type of motor is the same resistance that was used practically on most street cars at that time, in starting motors of any type.

Q. 32. Did you find this spot welding successfully performed that season?

A. I never found one that had given us any trouble by burning open.

Q. 33. And had the ribbon given you any trouble before?

A. Continual trouble, yes, sir.

Q. 34. Is this Smith machine in existence now?

A. It is not.

Q. 35. When was the last time you saw it?

A. It was really destroyed at the time of the flood that we had in that section of the country, and it laid in our shop cellar until we went to clean house, you might say, and we looked at the machine, and debated over it, and decided to scrap it. We have been sorry many times since that we did it. We still can find practical uses for it now more than we could at that time.

(Mr. Fish: When was that large one made?)

(The Court: Six years ago in March.)

(Mr. Pattison: Sample offered as Defendant's Exhibit 71, Illustrative Work Done on Smith Electric Welder.)

Q. 36. That is all.

Cross-examination by MR. SRACKFOLE:

X-Q. 37. On what kind of machine was this model made this morning?

A. On a Winfield machine.

X-Q. 38. In Detroit?

A. Yes, sir.

X-Q. 39. In what factory?

A. The—I had never seen the plant before. I don't know the exact name.

X-Q. 40. This Smith machine was originally intended for butt welding copper rods, and it failed on that?

A. On welding copper wire, yes, it failed on that.

X-Q. 41. And then it was used to butt weld the ends of these two bolts?

A. Yes, sir.

X-Q. 42. Was that successful?

A. Very successful.

X-Q. 43. And later, it was used to spot weld the ends of these iron ribbons? Is that the idea?

A. Yes, sir.

X-Q. 44. How much later was it used for the butt welding of ends of the bolts?

A. I would say at the same time, we were doing the same work all the time. I would not say which was done first, but if my memory serves me right, the bolts were butt welded first, more for curiosity through the mechanical department; our blacksmith doubted our ability to do it.

X-Q. 45. The bolts were spot welded first?

A. I could not remember that. I think so, but I cannot remember distinctly.

X-Q. 46. That was a good many years ago?

A. That was in 1905.

FRED G. CARTER.

FRED G. CARTER, after being duly sworn on behalf of the defendant, testified as follows:

Examined by MR. PATTISON:

Question 1. Where are you now living, Mr. Carter?
Answer. Warren, Ohio.
Q. 2. What is your business?
A. Machinist.
Q. 3. Where are you now working?
A. The Trumbull Steel Company, Warren, Ohio.
Q. 4. Did you ever work for the Winfield Manufacturing Company?
A. I did, sir.
Q. 5. Did you know Mr. Albert Taylor?
A. I knew Mr. Bert Taylor.
Q. 6. Was he at the Winfield Company while you were there?
A. Yes, sir, he was.
Q. 7. Do you know anything about any welding machine he had made?
A. Yes, sir, I had some experience on the welding machine Mr. Taylor made.
Q. 8. When was this?
A. As near as I can recollect, it was the year 1905.
Q. 9. When did you go with the Winfield Company?
A. I first went with the Winfield Company in 1904, the summer.
Q. 10. The summer of 1904?
A. Yes, sir.
Q. 11. What was the first work you remember of on the welding machine at the Winfield Company?
A. The first work I can remember was butt welding.
Q. 12. Does this drawing illustrate anything you saw at that time? (referring to Defendant's Exhibit 69).
A. There is a drawing on this sheet that well represents the first machine I did work on.
Q. 13. What kind of work was done on this machine?
A. The work done on this machine was butt welding the parts of elbows, bent elbows, one-piece elbow.
Q. 14. Was any other kind of work done on this machine?
A. Yes, sir; there was quite a bit of experimental work done on that machine.
Q. 15. What did that relate to?
A. It related to spot welds and the spot welding and butt welding.
Q. 16. On what?
A. On a butt welding machine.
Q. 17. What did you weld?
A. Small strips of sheet steel, as near as I can recollect.

Q. 18. Did you do any work on the machine referred to on this sketch?

A. Yes, sir.

Q. 19. What work did you do on this machine?

A. As near as I can recollect, I made the handle that operates the sliding head on this machine.

Q. 20. Did you operate it?

A. I have operated that machine.

Q. 21. What kind of welds did you make on it?

A. I made butt welds, and I have made spot welds on it.

Q. 22. What did you spot weld?

A. Small pieces of steel parts of elbows.

Q. 23. Did you ever see that machine before you?

A. Yes, sir, I have seen that machine.

Q. 24. Where did you see it?

A. At the plant of the Winfield Manufacturing Company at Warren, Ohio.

Q. 25. Did you see it operated?

A. I did.

Q. 26. This Exhibit 68, did you operate it?

A. I recall I did operate that machine then in an experimental way.

Q. 27. What did you do on that machine?

A. I have welded small pieces of steel, parts of elbows, in an experimental way.

Q. 28. Did it weld good?

A. It certainly did.

Q. 29. Do you know whether Mr. Taylor did any further work on electric welding machines at the Winfield Company?

A. I know that Mr. Taylor continued in that line of work.

Q. 30. When did you leave the Winfield plant?

A. To the best of my recollection, it was 1907. I am not positive.

Q. 31. Were you closely connected with the electric welder work all the time you were there?

A. I was.

Q. 32. In what way?

A. Being a machinist, I had considerable to do with the different machines made, and so forth.

Q. 33. What character of machine followed this Exhibit 68?

A. I would say the spot welder.

Q. 34. What was the general construction of it?

A. The general construction of the spot welder we completed was like this machine, I would say a six-inch machine, and there has been very little improvement, with the exception of the base it stood on and the operating switch.

Q. 35. I hand you a sketch and will ask you whether that represented the machine according to your recollection?

A. To the best of my recollection, that is the exact duplicate.

Q. 36. What was done with that machine?
A. I think that machine was put on the market. I am not positive. There was some work done with it in the shop.
Q. 37. The exhibit referred to is Defendant's Exhibit 70. Were other machines than the one like this Exhibit 70 built there?
A. There were.
Q. 38. Did you do any work on them?
A. I did.
Q. 39. Were any machines offered for sale while you were there?
A. Yes, sir, there were.
Q. 40. Were any sold while you were there?
A. To the best of my knowledge; they left the shop.
Q. 41. When you left there in 1907, were they still engaged in the manufacture of spot welders?
A. They were.
Q. 42. Do you know whether the Winfield Company used spot welders in the manufacture of their product?
A. They did at one time.
Q. 43. What did they use it for?
A. Welding seams and elbows.
Q. 44. "At one time." When was that?
A. That was the year 1906, I will say. I am not positive of that. It may have been before that.
Q. 45. Did any of this spot welding work go out to the trade?
A. Yes, sir.
Q. 46. What were the articles that were welded?
A. Stove-pipe elbows.
Q. 47. Did you see many of them manufactured for the market?
A. I did, quite a few.
Q. 48. In 1906?
A. Yes, sir.
Q. 49. Do you think it was not earlier than that?
A. It might have been earlier, possibly.
Q. 50. Then you were closely connected with Mr. Taylor's work?
A. I was.
Q. 51. Did he tell you where he first learned about welders?
A. No, sir, not to my recollection.

(Mr. Pattison: That is all.)

No cross-examination.

(The Court: Call the next witness.)

(Mr. Church: There is a witness on his way here.)

(The Court: We have at least an hour left.)

(Mr. Church: May I ask we take a recess for a few minutes?)

(The Court: Yes. I would like to get out of the building by at least 25 minutes to four.)

EVRAH C. LIPPS.

EVRAH C. LIPPS, after being duly sworn on behalf of the defendant, testified as follows:

Direct examination by MR. PATTISON:

Question 1. Your full name?
Answer. Evrah C. Lipps.
Q. 2. Where do you live?
A. Ninety-eight and one-half Moran Street, Detroit.
Q. 3. Where are you now working?
A. At the Packard Motor Car Company.
Q. 4. What are your duties there?
A. Foreman in the tool room.
Q. 5. How long have you been with them?
A. Nine years the fourth of last April.
Q. 6. Do you know Mr. Fred P. McBerty of Warren, Ohio?
A. Yes, sir.
Q. 7. When did you meet him?
A. In 1900. I don't know just exactly when first. I believe it was the year 1900 that I first saw him, as near as I can recollect.
Q. 8. Did you work at the Warren Electric & Specialty Company at any time?
A. Yes, sir.
Q. 9. When did you leave the employment of that company?
A. In 1901.
Q. 10. What time in 1901?
A. In June.
Q. 11. While you were working for the Warren Electric & Specialty Company, did you see an electric welder there?
A. Yes, sir.
Q. 12. Did you do any work on it?
A. Yes, sir. That is, it wasn't my duty to do the operating of it, but I saw the machine there all the time.
Q. 13. Did you do any welding on it?
A. I have occasionally, yes, sir, but not as a regular business.
Q. 14. What kind of welding did you do on it?
A. Butt welding, welding rings together.
Q. 15. Did you do any other kind of welding on it?
A. I cannot remember what welding was done on it, but there was other welding besides the butt welding. I know we welded fan blades.

Q. 16. What were they welded to?
A. To the center member.
Q. 17. Did you see any of these fan blades welded to the center members?
A. I don't recollect of seeing the fan blades themselves welded, but I saw them after they were welded.
Q. 18. You didn't see the work done, but you saw the fan blades after they were finished?
A. I saw the boys working on them. It has been so long ago I never paid any attention to it any more than that.
Q. 19. This was, of course, before you left there in June, 1901?
A. Yes, sir.
Q. 20. Do you think you could recognize that welder machine?
A. I think I would.
Q. 21. Examine this machine over here and see what you think it is.
A. Yes, sir, that is the machine.
Q. 22. Where did you see it?
A. The first time I saw it was at the Warren Electric & Specialty Company's factory.
Q. 23. That was before you left there in June, 1901?
A. Yes, sir.
Q. 24. Did you see any completed fan blades that were welded on this machine?
A. You mean on the fans, or do you mean——
Q. 25. I mean the four parts.
A. Yes, sir.
Q. 26. Did you see any put on the completed fan?
A. I saw them working on them. They would make a piece, the cross bars, and weld them on afterwards.

(By the Court):

Q. 27. You have no recollection of seeing any completed fans?
A. Oh, yes.
Q. 28. With the welds on? You have seen the assembled fans?
A. Not the assembled fans, but the four blades on.
Q. 29. The four blades on them?
A. Yes, sir.

(By Mr. Pattison):

Q. 30. I show you a sketch and ask you if you have seen that before?
A. Yes, sir. I believe, as nearly as I can see, that is the original sketch that machine was made after.

(The Court: Did you ever see the sketch before?)

(The Witness: Yes, sir, I saw the sketch itself.)

Q. 31. At the Warren factory?
A. Yes, sir.

(Mr. Pattison: This is the sketch, Exhibit M, attached to McBerty's affidavit, Exhibit 28.)

Q. 32. How did you happen to see that sketch at the Warrer Electric & Specialty Company's place?

A. Well, now, it was in the process of construction. I saw what was going on, the different machines, and Mr. McBerty would show us different methods and maybe make a sketch, and take them in the machine shop to have them worked up, and in my duty I would be from one place to another, and would naturally see them. I worked there some time, and saw a great many of the parts, and worked on them. It is so long ago it is now a hard matter to recollect the actual process of putting those parts together, and what I did make myself, and what I assembled, so long ago.

Q. 33. Did you, as a matter of fact, make any of the parts of that machine?

A. I assisted in making them, yes, sir.

Q. 34. Whom did you assist in making them?

A. Let me see—Mr. McBerty himself was one, and I think Mr. McDonald—no, it wasn't Mr. McDonald.

Q. 35. Maybe you can remember some of the gentlemen here in the room. Do you remember Mr. Powers of the Warren Electric & Specialty Company?

A. John Powers, yes, sir.

Q. 36. Jasper Powers?

A. Jasper Powers, yes, sir.

Q. 37. Did he help about this machine?

A. He was the man; I could not think of his name. I was trying to recall him. He was the foreman of the machine shop.

Q. 38. How many of these completed fan blades do you think you saw spot welded?

A. I could not tell you how many. I know we saw some. It was common talk in the shop, making them that way.

Q. 39. You left that company in June, 1901?

A. Yes, sir.

(Mr. Pattison: That is all.)

Cross-examination by MR. STACKPOLE:

X-Q. 40. Are you sure it is 1901 that you left the employ of that company?

A. Why, as near as I can recollect, it was.

X-Q. 41. Wasn't it 1900?

A. No, I think it was June. You see, I had a contract. In fact, I have that contract at my house, and when that expired, I left the employ and went into business for myself in Cleveland.

X-Q. 42. And was not that 1900?

A. If Mr. McBerty has my time book here, where I kept the dates of the men working there, I could tell. That would show the exact time.

X-Q. 43. Well, after you went to Cleveland, did you go back to Warren?

A. Yes, sir.

X-Q. 44. Into whose employ did you enter there?

A. From Cleveland I came back and went in with the Trumbull Manufacturing Company for about a month, awaiting an opening to come back into the old plant.

X-Q. 45. And did you finally go back into the old plant?

A. Yes, sir.

X-Q. 46. What year was that, if you remember.

A. Nineteen hundred and two, I think.

X-Q. 47. Nineteen hundred and two?

A. Yes, sir. I was away just a year. I left Warren in 1901 and I came back in September, 1902.

X-Q. 48. Do you recall a visit made to you by a Mr. Howe, and a Mr. McBerty in 1913, and the making of an adffiavit at that time?

A. Yes, sir.

X-Q. 49. And telling them all you knew about this matter of the spot welder?

A. Yes, sir.

X-Q. 50. You told him everything you knew then?

A. I told them all I could recollect at that time, yes, sir.

X-Q. 51. Did you give them any specimens or exhibits or anything else at that time?

A. They had all the exhibits that were available.

X-Q. 52. Did you make an affidavit?

A. Yes, sir.

X-Q. 53. Would you recognize that if you saw it now?

A. I think I would.

X-Q. 54. Do you remember whether you said in that affidavit:

> "I left the employ of the Warren Electric & Specialty Company in the summer of 1900, and went to Cleveland, Ohio, where I engaged in the manufacture of electric fans on my account. Attached hereto is the time book (marked Exhibit 'G') which I kept during this work in Cleveland, in which time time spent is marked beginning on August 20th, 1900, and continuing until April 29th, 1901, when I discontinued my Cleveland enterprise and went back to Warren, Ohio. I at first went to work for the Trumbull Manufacturing Company, where I remained but a few weeks."

Do you recall that?

A. Yes, sir. To get the exact date is a difficult matter, unless you

have something to refer to. That is the reason I fix that, was to have my old time book, and having given that up, I have no diary or notes or kept anything of that kind, that I could tell from, so I couldn't tell.

X-Q. 55 (Showing book). Is this your time book?

A. Yes, sir.

X-Q. 56. Does that help you in fixing the year?

A. Yes, I am in error. Has this been altered in any way?

X-Q. 57. Not that I know of.

A. This is 1900.

X-Q. Yes, I think you made a mistake in your testimony.

A. That is what I told you. It has been so long ago that all I could recollect from is previous data.

(Mr. Stackpole: I think we might save time if I simply put the affidavit in and asked him if he made the affidavit, and what is in it, and we can read it later.

(The Witness: I was under the impression it was 1901.)

(The Court: This is your time book?)

(The Witness: Yes, sir, the book I had when I was doing some experimental work in Cleveland. I was building a new fan entirely. This was just a time book I kept there with the dates on, and it happened I laid that aside. and I were working together, and we kept a record of each day of the work each of us were on. That is the way I fix the date in my mind.)

X-Q. 59. I show you an affidavit entitled: "In the United States District Court, District of Massachusetts. Thomson Electric Welding Company, et al., vs. Barney & Berry, Incorporated." Is that your signature to that affidavit?

A. Yes, sir.

X-Q. 60. Did you swear to that affidavit in October, 1913, as shown by that jurat?

A. I don't know what date it was, sir.

(Mr. Stackpole: That book goes in with the affidavit, does it not?)

(Mr. Church: Yes.)

X-Q. 61. Will you look that affidavit over and see if you recognize that as your affidavit made at that time?

A. I have had no occasion to remember that. I had nothing to refresh my mind on, and it is hard to accurately remember the dates. Let me read this. This was made when I had my copies of everything so that I could refer to it, and as I stated before,

when I go to remember these things, it is a very difficult matter to place dates. 1898, you see, is when I started to work with them. It was 1899, I think it was, the year after he came back to work there. He was not there when I first came there, when I first came to the Warren Electric Company, McBerty was not there. Then he came in afterwards. It is a hard matter to remember that. It was just a short time afterwards. Then you have a copy of my original contract?

X-Q. 62. It is attached thereto. You may look at it and see.

A. I would look at it to fix the date. The date of that contract would show the exact date.

(Mr. Fish: Let me find it for you. That is the contract there. The matter of dates is not of large consequence. I have no doubt the dates in your affidavit are right.)

A. By carrying this book, carrying one date after another, I could tell. I was with them there two years. That would be 1900. I was with them at that time experimenting. 1898, March 2nd, that is right, because I came there—well, I came there on the 25th of January, and this contract was made out the 2nd subsequent to the 25th of January.

(Mr. Stackpole: The dates are not of so much importance as whether you recognize that affidavit as the one you signed.)

A. I don't recollect that part of it being in there. That is right. You see, everybody was working with that machine.

X-Q. 63. Is this your affidavit? That is the question.

A. Yes, sir; yes, sir.

(The Court: That is all we want to know, whether that is your affidavit or not.)

A. Yes, sir.

X-Q. 64. You gave the information contained in that affidavit to Mr. Howe in Mr. McBerty's presence?

A. Yes, sir.

X-Q. 65. In that affidavit do you recollect giving him this information:

"When I was working with the Trumbull Company in 1901, as I have referred to, I frequently went to the works of the Warren Electric & Specialty Company to see Mr. Fred P. McBerty, with whom I was very friendly, and during these visits I saw an electric welding machine which was arranged as shown in the sketch given to Mr. McBerty last December and in the Exhibit 'A' attached to Brown's affidavit above referred to. At the time of my visit to Mr. McBerty in 1901 this

machine was used for butt-welding the rings of fan guards and I recall distinctly that on one of my visits I found Mr. McBerty changing the transformer which supplied current to the machine. The reason for this being that the transformer which had been used was not of large enough capacity to supply the current for welding the inner fan rings, so that the transformer became over-heated and the change consisted in putting in a transformer of large capacity so that sufficient current could be supplied"?

Is that correct?

A. He was putting in a new transformer, yes, sir.

X-Q. 66. The question is whether that statement there is correct. Is that statement correct as I read that?

A. As nearly as I could judge from it, yes, sir.

X-Q. 67. Do you recollect this sample attached to the affidavit?

A. I could not recall that. It looks very much like it. We had so many of those pieces laying around there, whether that is one or not, I could not say. It looks very much like it. In fact, I would say that it was, as near as I could judge, because the way they make the welds now is by bringing a heavier pressure on them, and they are dented in more.

X-Q. 68. Do you recall in that machine, in the case of the spot welded blades, that the blades were punched for rivet holes?

A. Originally, we riveted all of them.

X-Q. 69. And the blades were punched for rivet holes?

A. Yes, sir.

X-Q. 70. And in the four-bladed welded device, were they similar in character and size to Defendant's Exhibit H that you saw?

A. Very similar to that. It worked on that same principle exactly.

X-Q. 71. Now do you recall that the spot welding was not adopted as a commercial method of making those blades by the Warren Electric Company in 1901?

A. Yes, sir.

X-Q. 72. Do you know the reason why?

A. I could not tell you any more than it was a new thing, and they were a little skeptical about going into anything they were not thoroughly familiar with.

X-Q. 73. Do you recall the use of electrodes that were bent up in that machine?

A. Bent up in what way?

X-Q. 74. Put in the—well, I don't know. I will read what you say:

"I distinctly remember that at that time the space between the clamp arms 3 and 4 was not sufficiently deep to permit the sheets, to be welded together, to extend sufficiently low-

down when placed between the electrodes 31 and 32 when these electrodes were straight, and so we bent the ends of these electrodes upwardly so as to allow the sheets of metal to enter between the electrodes to a sufficient extent to place the weld at the spot desired."

That was done?

A. Yes, sir.

X-Q. 75. You recall that?

A. Yes, sir. You will notice that machine set on a different base from what you have got it attached there to now. It was on a bench.

X-Q. 76. Did it stick out as far as it does now?

A. It had been altered repeatedly. When first made, it set down.

X-Q. 77. Covered the whole bench?

A. Yes, sir.

X-Q. 78. Didn't stick out at all?

A. It didn't stick out at all first.

X-Q. 79. Later, you say it was moved out?

A. Yes, sir.

X-Q. 80. Do you recall in the original machine the fibre between the two base plates ran the whole length?

A. Yes, sir. That is why we could not get a sheet in between.

X-Q. 81. Did you tell Mr. Howe at that time that you had seen complete four-bladed welded spiders?

A. Very similar to that.

X-Q. 82. Did you tell Mr. Howe that?

A. I think I did, yes, sir.

X-Q. 83. Did you tell him you saw this going through the factory?

A. They were not going through the commercial part of it, no.

X-Q. 84. They were not?

A. No.

X-Q. 85. Just experimental?

A. Just experimental, yes, sir.

(Mr. Stackpole: We offer in evidence Mr. Lipps' affidavit as Plaintiff's Exhibit 30. I would like to have the Clerk mark this at once.)

(The Court: Yes, bring the clerk in to have them marked.)

(Mr. Stackpole: We would like these two marked, because they are important. I put the number up in the corner, and this should be attached.)

X-Q. 86. Do you recognize the exhibits attached to this affidavit, the contract between yourself and the Warren Electric & Specialty Company, and the other exhibits?

A. That was where we started our dating.
X-Q. 87. You recognize that exhibit?
A. Yes, sir.
X-Q. 88. Do you recognize that telegram that follows after that?
A. Yes, sir. I was down in West Virginia.
X-Q. 89. Do you recognize the next exhibit, another telegram?
A. Yes, sir.
X-Q. 90. Do you recognize the next one, which is a drawing?
A. That is one of them; that is the original.
X-Q. 91. That is the original, is it?
A. I think so. Mr. Powers——
X-Q. 92. When was that made?
A. Well, it was made before I went to Cleveland.

(The Court: Here is the Clerk. Now, Mr. Voorheis, there are several exhibits counsel want you to initial and mark at once. You may look at their original affidavits and at the same time you may include Defendant's Exhibit M, and give it particular care. I suggest you mark those exhibits and put them all in one package.)

(Clerk Voorheis: I will care for them. They will all go in one locker together. They will be under lock.)

X-Q. 93. This exhibit is correct in its statement of fact?
A. As near as I can remember. I have not read it all. As near as I could remember at that time. It was brought up to date, those other occurrences, so that I could bring one following the other. So that I knew at that time, but perhaps not so clearly now.
X-Q. 94. I would like to have your present recollection, whether you think that affidavit is correct?
A. I think it is correct, yes, sir.
X-Q. 95. That is all.

(The Court: Any re-examination?)

Redirect examination by MR. PATTISON:

Re-D. Q. 96. Do you know Mr. E. B. Craft?
A. I knew him, yes, sir.
Re-D. Q. 97. Was he at the Warren Electric & Specialty Company while you were there?
A. He was there, yes, sir.
Re-D. Q. 98. You were working at the same time he was?
A. Yes, sir.

(Mr. Pattison: That is all.)

(Mr. Stackpole: That is all, your Honor.)

(Mr. Church: That is all we have at this time.)

(The Court: I have about 17 minutes at your service.)

(Mr. Stackpole: It will not be worth while to enter upon anything further at this time.)

UNITED STATES DISTRICT COURT

EASTERN DISTRICT OF MICHIGAN

SOUTHERN DIVISION.

THOMSON SPOT WELDER COMPANY, Plaintiff.

vs.

FORD MOTOR COMPANY, Defendant.

In Equity. On Harmatta Patent No. 1,046,066.

Deposition of Francis S. Maguire, taken in behalf of the defendant, at the office of Messrs. Church & Church, 604 McGill Building, Washington, D. C., on the 28th day of May, 1919, before Thomas Durant, a notary public in and for the District of Columbia, pursuant to notice.

Present: Melville Church, Esq., in behalf of Defendant. H. M. Holmes, Esq., in behalf of Plaintiff.

FRANCIS S. MAGUIRE.

FRANCIS S. MAGUIRE, a witness produced in behalf of defendant, having been duly sworn, deposes and says, in answer to questions propounded to him by Mr. Church, counsel for the defendant, as follows:

Question 1. Please state your name, age, residence and occupation.

Answer. Francis S. Maguire; age, 37; Washington, D. C.; patent lawyer.

Q. 2. How long have you been engaged in the patent law business?

A. For the past fifteen years.

Q. 3. And how long have you been a member of the Bar?

A. Since 1904.

Q. 4. You were formerly associated in business with the late

J. Nota McGill, Esq., of this city, were you not?

A. I was.

Q. 5. During what period were you so associated with him?

A. From about 1899 through 1915.

Q. 6. When did Mr. McGill die?

A. October 16, 1915.

Q. 7. On his death, who succeeded to his business and became the custodian of his papers and files?

A. The firm of McGill & Maguire, of which I am a member.

Q. 8. What is your partner's name?

A. Grafton L. McGill.

Q. 9. And what relation did he bear to J. Nota McGill?

A. He was a brother of the late J. Nota McGill?

Q. 10. Please examine the paper I now show you and state, if you know, what it is and where it came from?

A. It is a letter from the National Electric Welder Company, dated April 20, 1914, addressed to J. Nota McGill, and produced from the files of McGill & Maguire.

Q. 11. How is that letter subscribed?

A. The National Elec. Welder Co., per F. P. McBerty, Sec. & Treas.

Q. 12. Are you familiar with the signature of F. P. McBerty, who appears to have signed this letter as secretary and treasurer of the National Electric Welder Co., and if so state whether or not you recognize the written signature forming part of this subscription as his?

A. I am familiar with the signature of Mr. F. P. McBerty, who signed this letter as secretary and treasurer and I recognize the signature as that of Mr. McBerty.

(Mr. Holmes: This question and answer are objected to as immaterial and irrelevant and as intended to prove a document by improper methods and by secondary evidence, no proof having been offered as to why this document cannot be proved by first hand evidence of the writer.)

Q. 13. I note on the face of this letter in the upper left hand corner, the following notation in pencil "4/22/14." State, if you know, what that indicates, and who made it?

(Mr. Holmes: Same objection.)

A. The notation is in the handwriting of the late J. Nota McGill and indicates the date of the reply to the letter of the National Electric Welder Company, it having been the custom of the office of the late J. Nota McGill to note the date of a reply to all letters in the upper left hand corner of the letters.

Q. 14. State whether or not you are familiar with the handwriting of the late J. Nota McGill?

A. I am.

(Mr. Church: The letter is offered in evidence as "Defendant's Exhibit No. 72, McBerty letter of April 20, 1914.

(Mr. Holmes: Introduction of this letter in evidence is objected to first, as the introduction of heresay testimony, secondly, as improperly proven. No basis has been made for proving this letter by secondary evidence and no opportunity given to plaintiff to cross-examine the writer of the letter on the contents thereof. The letter is immaterial, irrelevant and entirely improper and counsel for defendant is notified that a motion will be made in due course to strike the same from the record.

Q. 15. Please examine this second paper which I now show you and state if you know what it is and where it came from?

A. This is a letter from the National Electric Welder Company, dated February 1, 1913, addressed to J. Nota McGill and produced from the files of my firm, McGill & Maguire.

(Mr. Holmes: This question and answer are objected to for the reasons already stated in reference to the questions and answer as to the first letter introduced in evidence, and the objection is repeated to all further questions in reference to said letter.

Q. 16. How is this letter subscribed?

A. The National Elec. Welder Co., by Z. A. McBerty, Assistant Sec'y.

Q. 17. Who is Z. A. McBerty, if you know?

A. Z. A. McBerty is the wife of Mr. F. P. McBerty.

Q. 18. Are you familiar with the signature of Z. A. McBerty, who signed this letter as assistant secretary of the National Electric Welder Co., and if so state whether or not you recognize the written signature forming a part of this subscription as hers?

A. I am familiar with the signature of Z. A. McBerty and recognize that subscribed to the letter as her signature.

Q. 19. I notice on this letter at the upper left hand corner the notation "2/3/13." In whose handwriting is that and what does it indicate?

A. The notation is in the handwriting of the late J. Nota McGill and indicates the date of the reply to the letter upon which it appears, namely, February 3, 1913.

Q. 20. I believe you did not say what the notation "4/22/14" on Defendant's Exhibit No. 72 means. Will you please state what it means?

A. The numerals "4/22/14" on Defendant's Exhibit No. 72, indicate April 22, 1914.

Q. 21. The letter of February 1st, 1913, is offered in evidence as "Defendant's Exhibit No. 73, McBerty letter of February 1, 1913."

(Mr. Holmes: Plaintiff objects to the introduction of this letter in evidence for the reasons stated above in the objection to the first letter introduced in evidence at this hearing and notice is repeated that a motion will be made in due course to strike this letter from the evidence.)

Q. 22. Are we to understand that these two letters—Defendant's Exhibit No. 72 and Defendant's Exhibit No. 73—are produced by you from the files of the late J. Nota McGill which came into the possession of your firm as the successor to his business?

A. That is correct?

Q. 23. State whether or not you are able to say whether the notation "4/22/14" on the upper left hand corner of Defendant's Exhibit No. 72, and the notation "2/3/13" on the upper left hand corner of Defendant's Exhibit No. 73 were applied in due course of business and according to the common practice in the office of the late J. Nota McGill?

(Mr. Holmes: This question and the preceding question and all further questions with respect to these letters is objected to as immaterial and irrelevant, the letters not being properly in evidence.)

A. The notations "4/22/14" and "2/3/13," appearing upon the Exhibits Nos. 72 and 73 were applied in the due course of business and according to the common custom in the office of the late J. Nota McGill, no receiving stamp being used in the office to indicate the date of receipt, but the date of reply being always applied by pencil notation in the upper left hand corner.

Cross-examination by MR. HOLMES:

X-Q. 24. Have you in your office a file of Mr. McGill's correspondence including copies of letters which he himself wrote during the period of his practice?

A. We have nearly all of the files made up during the practice of the late J. Nota McGill, which include the letters addressed to Mr. McGill, and we have the letter books in which all letters written by Mr. McGill are letter pressed, with the possible exception of letters written in the earlier part of his practice and up to about 1895.

X-Q. 25. Will you please produce the letter press copy of the letter which Mr. McGill wrote to Mr. McBerty under date of April 22, 1914, in reply to the letter of April 20th, 1914, from Mr. McBerty, introduced in evidence as Defendant's Exhibit No. 72?

A. I have here our letter press book numbered 54 and wherein is a press copy of the letter from Mr. J. Nota McGill to the National Electric Welder Co., dated April 22, 1914.

It is stipulated that a copy of the letter may be read into the record from the letter book, the letter itself to be retained in the possession of Mr. Maguire.

The letter is as follows:

"22nd April, 1914.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I appreciate getting your letter of the 20th instant. There are many things which I do not understand as to the trial at Boston. Somebody got a case of weak knees or was it a case of cold feet? I cannot possibly understand the failure to lay foundation in the answer for your evidence. There is so much to consider that I prefer to defer saying anything more until I see Mr. McBerty, either here or in Warren.

I am today writing Mr. Edwards for information.

Very truly yours,

J. NOTA MCGILL.

M.I."

X-Q. 26. Will you please produce a copy of Mr. McGill's letter to Mr. Edwards and Mr. Edwards' reply thereto?

A. The copy of the letter from Mr. J. Nota McGill, dated April 22, 1914, to C. V. Edwards, Esq., is produced, being a press copy of the letter which is in our letter book No. 54, and Mr. Edwards' letter in reply, dated April 27, 1914, addressed to J. Nota McGill, Esq., is produced from our file.

The letter from Mr. McGill to Mr. Edwards follows.

"22nd April, 1914.

C. V. Edwards, Esq.,
No. 2 Rector Street,
New York.

Dear Mr. Edwards:

I hear that the testimony has been taken in open court in the suit on the Harmatta patent. What is the outlook? I also understand, in a general way, that McBerty's testimony was objected to for failure to lay foundation therefor in the answer. Is my understanding correct? I will appreciate any information you may give me.

Very truly yours,

J. NOTA MCGILL.

M.I."

Mr. Edwards' letter to Mr. McGill follows.

"EDWARDS, SAEGER & WOOSTER
Counsellors at Law
United States Express Building
2 Rector Street, New York

Clifton V. Edwards (4175)
Lawrence K. Sager Telephone (4176) Rector
Julian S. Wooster Cable Address
Edwayer New York.
April 27, 1914.

J. Nota McGill, Esq.,
McGill Building,
Washington, D. C.

Dear Sir:—

I have your letter of the 22nd. The taking of testimony in the suit on the Harmatta patent was completed and the case adjourned to be argued at a date to be fixed by the Court. This date has not been fixed. It is true that McBerty's testimany regarding earlier use was objected to and excluded upon the ground that such use was not set up in the answer. Mr. McBerty, however, gave very valuable testimony along other lines. It is, of course, impossible to form any accurate estimate of the outlook, but we have very strong hopes.

Yours very truly,
C. V. EDWARDS.

CVE.-G."

Indorsed on the upper left hand corner is the notation "4/30/14"

X-Q. 27. Will you please explain the notation "LB 50 page 911" on Defendant's Exhibit No. 73?

A. That has reference to letter book 50, page 911, wherein is pressed the reply to the letter of the National Electric Welder Co. of February 1, 1913.

X-Q. 28. Will you please produce a copy of that letter?

A. I produce letter book No. 50, where at page 911 is a letter from J. Nota McGill, dated February 3, 1913, to the National Electric Welder Co., reading as follows:

"3rd February, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I have your letter of the 1st instant and also the blade welded in 1901.

Mr. Fish advises me that he may be able to make an appointment for some day next week.

Very truly yours,
J. NOTA MCGILL."

X-Q. 29. I note on the letter press copy of this letter the notation in pencil "852." Will you please explain that notation?

A. The numerals in pencil "852" refer to the previous letter in letter book 50, addressed to The National Electric Welder Co., which is dated January 29, 1913.

X-Q. 30. The notation on each letter press copy of the page whereon is copied the previous letter written to the same person was the invariable practice in your office. Is that true?

A. That is correct.

X-Q. 31. Will you read into the record the letter of January 29, 1913?

A. The letter reads as follows:

"29th January, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I received your telegram yesterday, and in the next mail will doubtless have the Harmatta file.

I have asked Mr. Fish to designate some day next week when I may see him in New York.

Please send me one of the fan blades which was spot-welded in 1901 or thereabouts. I mean one of the two which Mr. McBerty showed me when last in Warren. Let him mark it in some way so that he can hereafter identify it when returned.

I am engaged in looking up the law on the question, and hope to report in a day or two.

Very truly yours,

J. NOTA MCGILL.

Later— I have your letter of the 28th instant and the Harmatta file wrapper.

I suggest that Mr. McBerty go to Cincinnati but pay his own expenses. Listen to what they have to say, but state that without consulting the other officers of the Company he is in no position to commit the National. After he learns what action is to be taken by the different parties he will confer with his associates and then advise them in the premises. Until his associates know what the others intend to do, and how they intend to take care of the National in the proposed deal, he is in no position to disclose the evidence upon which he may rely should suit be brought against us.

JNM

X-Q. 32. Will you please show me the letter from The National Electric Welder Co., under date of "the 28th instant" referred to by Mr. McGill in the letter of January 29, 1913?

A. I hand you the letter of January 28, 1913, from The National Electric Welder Co. to J. Nota McGill, reading as follows:

"Warren, Ohio January 28th,
1913,

J. Nota McGill,
Attorney At Law,
Washington, D. C.
Dear Sir:—

Your favor of the 27th inst., at hand, and are pleased to note Mr. Fish is sufficiently interested in your evidence to suggest a meeting. If possible we will be pleased to have you take the matter up with him Thursday.

We are forwarding by registered mail today, the file wrappers of the "Harmatta" case, but beg to advise this is a copy supplied us by the Winfield Co. Mr. Warren of The Toledo Elec. Welder Co., sent his copy to the Winfield Co., suggesting they make a copy for themselves and the National Co., which they did, but we would not want to guarantee the same as being a duplicate of the original.

We are enclosing herewith copy of a letter received from Mr. Warren, and are pleased to note that this company are deeply interested in preventing the National Co., from doing anything which might cause us future anguish.

Thanking you for past favors, and hoping the matter under consideration can be arranged to the satisfaction of all parties concerned, we are

Very respectfully yours,
THE NATIONAL ELEC. WELDER CO.
per
F. P. MCBERTY,
Sec'y and Treas.

FPM/ZM.

P. S. Your advise regarding the advertising the situation between the Thomson Co., and ourselves will be heeded, and will let the matter rest as it is for the time being."

X-Q. 33. Please produce the letter received from Mr. Warren referred to in the letter of January 28, 1913, as enclosed therewith?

A. The copy of the letter referred to in the letter of The National Electric Welder Co. of January 28, 1913, is produced, and reads as follows:

"COPY.
THE TOLEDO ELECTRIC WELDER CO.
Cincinnati, Ohio.
Jan. 25-1913.

Mr. F. P. McBerty,
c/o National Electric Welder Co.
Warren, Ohio.

Dear Sir:—

Yours of the 24th at hand, and the matters we want to talk over with you can be discussed at a personal interview better than in any other way. If you will come to Cincinnati, we will be very glad to pay your expenses, and would ask that

you arrange to come at as early a date as possible, as we believe it of sufficient importance to go over the matter we have in mind, to drop everything else at the present time, to get together. If you will accede to our proposal to come here we will explain the proposed deal, and it is not our intention to have you left out as long as we originally started in to work together. There was a disposition on the part of some parties to ignore the National Co. but this we would not allow. We were invited to attend a conference in Cleveland, and expected to see you there, but found that you were not expected.

We trust that you will accept our suggestion and come here at the earliest possible moment, as we believe a definite decision will be reached within the next week as to what action will be taken by the different interests, and we believe it of more importance to you than ourselves to have a meeting very quickly.

Yours respectfully,
(Signed) F. W. WARREN."

X-Q. 34. After the death of Mr. McGill, did the firm of McGill & McGuire continue as attorneys for the National Electric Welder Co. or Mr. McBerty?

A. The firm of McGill & Maguire has represented The National Electric Welder Co. and Mr. McBerty.

X-Q. 35. Has that representation continued to the present time?

A. Yes.

X-Q. 36. Have you in your files any correspondence between Mr. J. Nota McGill and The Toledo Electric Welder Co., or any officer thereof?

A. That I could not say without an examination of our files.

X-Q. 37. Will you please examine your files during the year 1910 and state whether or not there was any such correspondence?

(Mr. Church: Counsel for defendant objects to this line of examination as not proper cross-examination. The cross-examination of this witness has already gone far afield. In respect of other matters than those upon which the direct examination of the witness was predicated plaintiff is entitled to call the witness as its own witness. Having, however, no purpose to restrict the cross-examination beyond reasonable limits, counsel for defendant asks counsel for plaintiff his purpose in asking the last question put.)

(Mr. Holmes: Counsel for defendant in the hearing at Detroit and at this hearing has introduced in evidence letters and copies of letters to and from Mr. McGill, having an alleged bearing on an alleged use of the process of the patent in suit by Mr. McBerty in the year 1901 and also as having an alleged bearing on the question of the conduct of a suit by the Thom-

son Electric Welding Company against Barney & Berry. Counsel for defendant has thereby opened up the files of Mr. McGill and used such letters as he desired to produce having alleged bearing on these matters and it is manifestly improper for defendant to use part of this file without producing the whole file.)

(Q. 37 is repeated.)

(Mr. Church: Counsel for defendant replies that this witness was produced for the purpose of identifying and proving two letters from The National Electric Welder Company to the late J. Nota McGill, Esq., and the proposed continuation of his cross-examination is deemed to be, under Federal Practice, entirely incompetent, irrelevant and immaterial and not proper cross-examination, and the witness is advised that he may not make answer to the last cross-question proposed, unless directed to do so by order of court.)

A. I decline to answer the last question unless directed so to do by a court of competent jurisdiction.

X-Q. 38. Have you in the files of your office any correspondence between the late J. Nota McGill or the firm which succeeded him, and the Toledo Electric Welder Co., or any officer thereof which has reference to or mentions a certain claim of one F. P. McBerty to have used the process of spot welding in the years 1901-2 or 3 at Warren, Ohio, or which has reference to or mentions any fan blades alleged to have been spot welded by Mr. McBerty, as aforesaid, or which mentions or has reference to the defense by the Toledo Electric Welder Co., of a suit brought by the Thomson Electric Welder Company, in which the Toledo Electric Welder Co. was interested. I limit my question to correspondence beginning in the year 1910.

(Mr. Church: Question objected to as incompetent, irrelevant and immaterial and not proper cross-examination and the former suggestion to the witness is repeated.)

A. I decline to answer the foregoing question except under authority of a court of competent jurisdiction.

X-Q. 39. Will you please produce such correspondence between J. Nota McGill and the Toledo Electric Welder Co. as may refer to or mention each or any of the matters outlined in X-Q. 38?

(Mr. Church: Last objection repeated.)

A. The answer to the preceding question is repeated as answer to this.

X-Q. 40. Were all letters written by the late J. Nota McGill to Mr. McBerty addressed to The National Electric Welder Co.?

A. I cannot answer definitely as to this because there may have been some letters directed to Mr. McBerty personally.

X-Q. 41. Will you please determine from your files whether there are copies of any letters addressed to Mr. McBerty personally, commencing the year 1910?

A. I shall be very glad to do so.

X-Q. 42. Have you examined the file of Mr. McGill's correspondence commencing the year 1910 to determine whether or not there are any such letters?

(Mr .Church: Same objection.)

A. I have not done so.

X-Q. 43. Will you please do so?

(Mr. Church: Same objection.)

A. That will require a considerable amount of time.

X-Q. 44. I asked you if you would so so?

(Mr. Church: The objection is repeated and the witness is instructed that he need not make the examination suggested without an order of court directing him to do so.)

A. If directed by an order of a court of competent jurisdiction I will make the examination.

X-Q. 45. Do you decline to do so unless so ordered?

A. I do.

X-Q. 46. Will you kindly produce any copies of letters which there may be in the files of your firm from Mr. McGill to Mr. McBerty, having reference to or mentioning an alleged use by Mr. McBerty of the process of spot welding at Warren, Ohio?

(Mr. Church: Same objection and direction.)

A. I will not produce any such letters except under authority of court.

X-Q. 47. Will you produce any letters or copies thereof which may be in your files from the late Mr. McGill to Mr. McBerty, having reference to or mentioning any fan blades alleged to have been spot welded by Mr. McBerty, at Warren, Ohio, or mentioning or having reference to the conduct by the Toledo Electric Welder Co. of a suit brought by the Thomson Electric Welding Co., in the defense of which the Toledo Co. was interested? I ask you to produce letters or copies thereof having relation to or mentioning either or both of these matters?

(Mr. Church: Same objection and direction.)

A. Same answer as to the preceding question.

X-Q. 48. The letter of January 29, 1913, quoted in the record, in answer to X-Q. 31, has the notation at the top "817." Will you

please produce the letter at page 817 which according to your testimony this notation refers to?

A. I produce letter book No. 50, where at page 817 there is a letter dated January 27th, 1913, addressed to The National Electric Welder Co., which reads as follows:

"27th January, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I enclose herewith a copy of a letter I have just received from Mr. Fish, the Thomson Company's attorney, and a copy of my reply. Do you want me to go to New York to confer with Mr. Fish?

I have your letter of the 24th instant. At this stage of the matter do not advertise your attitude in respect to the Thomson Company. I think the subject of bond should remain in abeyance until after Mr. Fish and I conclude negotiations. What I want is to get you out of this trouble or to secure some terms for you without including either of the other companies. Evidently they are carrying on negotiations independently of you, and naturally are looking out for their own ends. When they feel the helplessness of their situation they recall your existence.

If the Thomson people decline to deal with us, we can then arrange with a surety company for bond and also determine on the advertising policy.

I note that William Smith, now of Charleston, West Virginia, recalls the use of the spot welder. If necessary, I will prepare an affidavit for him to execute.

Yes, I would like to see the Harmatta file *at once* before I either see or communicate with Mr. Fish.

Very truly yours,

J. NOTA MCGILL.

Enclosure."

X-Q. 49. Will you please produce the letter from National Electric Welder Co. to Mr. McGill, of January 24, 1913, referred to in this letter of January 27th?

A. I produce a letter from The National Electric Welder Company, dated January 24, 1913, to J. Nota McGill, which reads as follows:

"Warren, Ohio, January 24th, 1913.

J. Nota McGill,
Attorney At Law,
Washington, D. C.

Dear Sir:—

We have been requested by a number of firms, among others The General Fireproofing Co., in Youngstown, O., to

give them a bond to protect them against incurred expense of litigation, due to the threats made by The Thomson Co. The writer had some conversation with Mr. White of the above mentioned company, who suggested that if I was in a position to put up a good fight with the Thomson Co., on this spot welding proposition, it might be policy to advertise the fact.

I am therefore writing to ask whether you could take up this matter of patent situation, and our ability to prove a good case with a representative of some good bonding company. For instance, The American Surety Co., and go over with their attorney the situation in detail, and if they consider our chances as good we have no doubt but they would bond us for a reasonable price of a machine, we would then advertise the fact that we would sell our machines with a guaranteed bond with some surety company. This would result in attracting considerable attention to the NATIONAL" welders, and enable us to secure a line of business which would not be in competition with the Toledo and Winfield Co's, due to the fact that they would not dare to advertise in such a manner themselves, and it would also bring to a head the patent situation between the Thomson and National Co's, promptly.

As I look at the situation, the Thomson Co., may consider the National Co., as being very small, not spending much money pushing the business, and for this reason think it policy to ignore us entirely and continue their intimidation in advertising, with the result they would check the efforts of the Toledo and Winfield Co's., and unless we started something ourselves we would never get to a final show down at all.

I will be pleased to have you express your opinion on this subject at your earliest convenience, and also advise us whether you consider it policy to give a bond covering the sale price of a machine.

In connection with our evidence we have been securing, I have located another witness to the building and demonstrating of the old welder, in the person of William Smith formerly of this city, who is now superintendent of some firm in Charleston W. Va. I was talking with him this A.M. and he remembers very well the use of the machine as a spot, butt welder, also as a welding machine for welding wire, such as is covered by the "Clinton" patents. Mr. Smith was employeed by The Warren Elec. and Specialty Co., in 1899, 1900 and he has been with The Peerless Elec. Co., until about one year ago. He is a man of un-questionable integrity, is exceedingly well liked and well known in this city, and further more has a wide range of electrical knowledge. He can identify the changes that have been made on the old machine, remembers how it was originally built, and did considerable work on the machine himself. He was very much interested in the welder as it was the first machine of the type he ever saw. If you

think it policy, and will outline the statement, Mr. Smith will be glad to supply all the information he possibly can, the same as Powers, Lipps and Brown.

We were in receipt of a letter from Mr. Warren, of The Toledo Elec. Welder Co., as per enclosed copy. We are also enclosing herewith copy of our reply. The writer thinks it policy to keep on friendly terms with The Toledo Co.

Hoping to have the pleasure of hearing from you at an early date regarding the matters mentioned, we are

Very respectfully yours,
THE NATIONAL ELEC. WELDER CO.
per
F. P. McBERTY,
Sec'y and Treas.

EPM/ZM

P.S. We have just been in receipt of the copies of file wrappers of the Harmatta case, from The Winfield Co. These were sent by Mr. Warren. Would you care to have copies?

X-Q. 50. Will you please produce the copy of the letter from Mr. Warren and the copy of the reply from Mr. McBerty referred to in the letter of January 24, 1913, just read into the evidence?

A. I produce copy of letter dated January 23, 1913, from Warren to National Electric Welder Co. and a copy of a letter dated January 24, 1913, addressed to The Toledo Electric Welder Co., attention Mr. F. W. Warren, from The National Elec. Welder Co. These letters read as follows:

"COPY.
THE TOLEDO ELECTRIC WELDER CO.
Cincinnati, Ohio.

Jan. 23-1913.

National Electric Welder Co.
Warren, Ohio.

Gentlemen:

We wrote you a short time ago regarding an interview that was to be held with representatives of the Thomson and Universal Co. The appointment was made by the Winfield Co. and Mr. Macneale and the writer went to Cleveland to attend the meeting. A proposition was put up to us, but we told them very plainly that your company would have to be included in any arrangement that was made.

Mr. Lachman went back East, but is going to return in a week or ten days and we believe it of the utmost importance that Mr. McBerty meets us before that time. We cannot very well enter into details of the proposition by correspondence, and would ask if he can come here to talk over the matter, as we firmly believe it is to his interest to do so. We would

like to have a meeting at the earliset possible moment, and if Mr. McBerty is not at home, will you kindly let us know where he can be reached by wire or letter so that we can make an appointment with him?

Very respectfully yours,
THE TOLEDO ELECTRIC WELDER CO.
(Signed) FRANK WARREN."

"Copy.

"January 24th, 1913.

The Toledo Electric Welder Co.,
Cincinnati, O.

Attention Mr. F. W. Warren.

Gentlemen:—

Re. yours January 23rd, 1913.

We have noted that you were present at a meeting held by representatives of the Universal and Winfield Co's, and the writer is surprised that Mr. Winfield did not notify the writer. In line with this same information beg to advise we have not heard a word from Winfield since the meeting at The Park Hotel, some time since.

There is no doubt but the Winfield Co., are doing all they can to eliminate the National Co., from this arrangement and under the circumstances it is entirely satisfactory.

The writer has been out of the city most of the time since you were here and am leaving again today for a few days, but expect to return within three or four days, will advise definite date of meeting when I return, if possible.

I note that Lackman is the man you are apparently dealing with, and am wondering why you are not dealing directly with the Thomson Co., as I understand Lackman is absolutely independent of the Thomson Co., other than his connection in a business way through the sale of the machines. It would seem to the writer that the Thomson Co., would be the ones to deal with.

Lackman's only interest is in lining up the independent manufacturers so as to get a good proposition to lay before the Thomson Co., which will enable them to hold the Thomson Co., to their present arrangement, which is apparently satisfactory to the Universal Co. Any arrangements made with Lackman will finally have to be sanctioned by the Thomson Co., and inasumch as the Universal Co., have no controlling vote or further interests in this other company, the writer cannot see how any agreement that is made can amount to anything more than merely putting the Universal Co., in a better position to deal with the Thomson Co.

Kindly let me hear an expression of your opinion regarding the subject mentioned.

We are pleased to advise that the Winfield Elec. Welding Machine Co., sent us a copy of the file wrappers of the Harmatt case.

Hoping to have the pleasure of seeing you within a short period, we are

Very respectfully yours,
THE NATIONAL ELEC. WELDER CO.
per
FPM/ZM *Sec'y and Treas.*"

X-Q. 51. In order to save time will you kindly produce for my inspection the complete file of correspondence between the late Mr. McGill and The National Electric Welder Co., commencing the year 1910?

(Mr .Church: Objected to as incompetent, irrelevant and immaterial, and not proper cross-examinatoin and the witness is directed not to answer unless required by an order of court.)

A. I decline to do so unless by order of court.

X-Q. 52. Will you please produce a complete file of the correspondence between The National Electric Welder Co. and the late Mr. McGill having any reference to the matter of any alleged spot welding alleged to have been done by Mr. McBerty at Warren, Ohio, in the year 1901, or having any reference to the case brought by the Thomson Electric Welding Company against Barney & Berry, in which the Toledo Electric Welder Co. was interested or having any reference to certain fan blades alleged to have been spot welded by Mr. McBerty at Warren, Ohio, in 1901?

(Mr. Church: Same objection and instructions.)

A. Same answer as to previous question.

X-Q. 53. Do you decline to produce any further correspondence between the late Mr. McGill and The National Electric Welder Co. relating to any of these matters.

(Mr. Church: Same objection and instructions.)

A. I do.

X-Q. 54. Please produce any correspondence which may have been had between the firm of McGill & Maguire and The National Electric Welder Co. having any reference to any of the matters referred to in X-Q. 52?

(Mr. Church: Same objection and instructions.)

A. I must decline to do so unless ordered so to do by a court order.

X-Q. 55. Will you produce the correspondence in your files between the late Mr. McGill and the firm of Edwards, Sager & Wooster, or Mr. Edwards, of that firm, or Mr. Thomas Howe, having any reference to the matters mentioned in X-Q. 52?

A. I must decline to do so, unless authorized by court order.

X-Q. 56. Will you please produce the copy of the letter referred to by the notation "659" on the copy of the letter of January 27, 1913?

A. The letter on page 659, Letter Book 50, is produced, and reads as follows:

"11th January, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I have your letter of the 9th instant enclosing second affidavit of Mr. Frank G. Brown. I have not yet heard from the Thomson Electric Welding Co., but this is not surprising.

At present I expect to be in Columbus on Thursday instead of Wednesday of next week, and if Mr. McBerty will be at Warren on Friday, I will go there from Columbus, but not unless I am first advised that he will be in Warren.

Very truly yours,

J. NOTA MCGILL."

X-Q. 57. Will you please produce the letter of January 9th to Mr. McBerty, referred to in this letter of January 11th? Witness will please produce letters without reading them unless requested by counsel.

A. I produce letter of January 9, 1913, from The National Electric Welder Co. to J. Nota McGill, which reads as follows:

"Warren, Ohio, January 9th, 1913.

J. Nota McGill,
Washington, D. C.

Dear Sir:—

We are enclosing herewith revised statement from Frank G. Brown, Detroit, Mich. Our Mr. F. P. McBerty is in Detroit at the present time, having been there several days getting his evidence into shape.

He wishes us to advise you that on talking with Mr. Brown, he finds that his first statement was not quite correct, as he had confused the welder with a platinum cutting and welding machine which was built for the Warren Electric & Specialty Company.

Mr. McBerty will be in Warren either Saturday morning or Sunday morning, and will proceed to have photographs taken of the small welder, and no doubt, he will be ready for you by Tuesday or Wednesday of next week.

We will wire you just when we think it advisable for you to come to Warren.

Thanking you for past favors, we are

Very respectfully yours,

THE NATIONAL ELEC. WELDER CO.

per

ZAM/LS *Assistant Sec'y.*"

X-Q. 58. Will you please produce the letter referred to by the notation "612" on the letter press copy of the letter of January 11th, 1913?

A. The letter appearing on page 612 of Letter Book No. 50 is as follows:

"8th January, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I have your favor of the 6th instant enclosing statement of Mr. J. W. Powers. I may be in Columbus on Wednesday next, the 15th instant, and if so I shall spend the next day in Warren.

Very truly yours,

J. NOTA MCGILL."

X-Q. 59. Will you kindly produce the letter of January 6th referred to in this letter?

A. The letter of January 6th referred to in the letter from J. Nota McGill to The National Electric Welder Co., of January 8th, 1913, reads as follows:

"Warren, Ohio, January 6th, 1912.

J. Nota McGill,
Washington, D. C.

Dear Sir:—

Your favor of the 4th inst., received.

Mr. McBerty is in Detroit, Mich., and the writer has forwarded your letter to him. Mr. McBerty will no doubt advise you from Detroit just when he thinks advisable for you to come to Warren.

We are enclosing herewith statement taken from Mr. J. W. Powers. This statement was taken here at the office Sunday the 5th inst., dated the 4th, and Mr. Powers took the original statement back with him to Findlay and will have the same sworn to before a NOTARY PUBLIC, today.

Very respectfully yours,

THE NATIONAL ELEC. WELDER CO.

per

Z. A. MCBERTY,
Assistant Sec'y and Treas.

ZAM"

X-Q. 60. Have you the statement taken from Mr. J. W. Powers referred to as enclosed in this letter?

A. No, I have not.

X-Q. 61. Will you produce Mr. McGill's letter of January 4th, 1913, referred to in the last letter just produced?

A. The letter referred to is on page 567 of Letter Book No. 50 and reads as follows:

"4th January, 1913.

The National Electric Welder Co.
Warren, Ohio.

Dear Sirs:

Re: Thomson Electric Welding Co.

I note all that you say in your favor of the 2nd instant. Please let me have a photograph or several of them taken at different angles of the spot welding machine which was constructed in 1901. To be of value as evidence of prior use it must not appear that this was a mere abandoned experiment, but it must be shown that the machine was used for spot welding. If the evidence is not sufficient to substantiate our allegation of prior use, it may be sufficient to substantiate our allegation of prior knowledge.

I have written the Thomson (not Thompson) Electric Welding Company, and enclose herewith a copy of my letter. I ought to see the machine you have in your custody before it is submitted to the attorney for the Thomson people. I entertain no doubt that I shall soon hear from their attorney and that he will want to see the machine. Before showing it to him I want to understand it more clearly. The affidavits submitted are not wholly sufficient, but I do not want to suggest any change until after I see the machine. I take it that you have not involved yourselves with other manufacturers of spot welding machines and that, so far as this matter is concerned, you want to protect yourselves. If the Thomson people will grant you a license, you can afford to surrender your evidence. If they will not grant you a license, you might arrange then with the Toledo people that in consideration of placing in their hands the evidence you possess they are to pay three-fourths of the expense of any litigation that may be brought either against you or themselves. My idea is to ignore the Winfield Company.

I am inclined to think it is policy to hunt for business and promise your customers that you will take care of them. I cannot say more than this until I see the machine. I do not like to put you to the expense of my going to Warren solely for that purpose, but I think it would be advisable to have me make the trip even though nothing else calls me in that direction. The matter can stand for the time being if Thom-

son's attorney does not promptly take up the subject, but once he communicates with me then I will have to arrange to see the machine before showing it to him.

Very truly yours,

J. NOTA MCGILL.

Enclosure"

X-Q. 62. Will you turn to Letter Press Book No. 54 and produce the letter shown therein from Mr. McGill to The National Electric Welder Co. next after that of April 22, 1914, which you read in the evidence in answer to X-Q. 25?

A. On reference to that letter I find that it pertains to the payment of a final Government fee on an application for patent.

X-Q. 63. Will you kindly show me the copy of the letter from Mr. McGill to the National Electric Welder Co. next after April 22, 1914, having any reference to the case of Thomson Electric Welding Co. vs. Barney & Berry, or to any alleged spot welding done by Mr. McBerty at Warren, Ohio, in 1901?

A. The next letter in Letter Book 54, following that of April 22, 1914, having any bearing on the matters referred to in the question is one appearing at page 555 and which reads as follows:

"30th April, 1914.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

Upon my return this morning I find your letter of the 24th instant and also one from Mr. Edwards. He tells nothing of importance, and fails to explain why he did not amend his answer to lay foundation for your testimony as to priority.

Very truly yours,

J. NOTA MCGILL.

M.I."

X-Q. 64. Will you please produce the letter under date of January 2nd, 1913, referred to in the letter of January 4th, 1913, which you produced in answer to X-Q. 61?

A. The letter referred to reads as follows:

"Warren, Ohio, Jan. 2nd, 1912.

J. Nota McGill,
Washington, D. C.

Dear Sir:—

We are enclosing herewith copy of notification regarding the patent situation, from the Thompson Co. We are also sending statements made by Mr. F. G. Brown, Detroit, Mich. and Mr. E. C. Lipps, Detroit, Mich. These gentlemen are old shop mates of the writers, and men with excellent mechanical ability.

I am leaving tonight for Detroit and will take up with Mr. Brown the matter of the date on his statement covering the time of the electric welder, as you will note his date is 1900, while Mr. Lipps date is 1901. This is apparently a mistake made by the stenographer in making it 1900 instead of 1901.

As I advised you before I have with me here at the factory the old welder which was originally designed for a butt welder, but on which we did the spot welding, together with the transformer which was used in connection with the machine. We also have the original factory records which shows the date on which this transformer was designed, and would further say the transformer was designed and built for a pneumatic wheel company in New Jersey to enable them to find out what voltage was necessary to give the proper results in welding, and was sent out for that purpose. After the company had used it they returned it to The Warren Elec. and Specialty Co., and they then built them a larger welding transformer for their machine.

The small welding transformer which was returned to The Warren Elec. and Specialty Co., was then turned over to the fan motor dep't and was used in connection with this electric welding machine. The date of the manufacture of this transformer was June, 1900, and the transformer was returned to The Warren Elec. and Specialty Co., in the fall of the same year. The same was turned over to the fan motor dep't Jan. 25th 1901.

Mr. McCurdy, who has been with the Warren Elec. and Spec. Co., and The Peerless Elec. Co. for years, also my partner in the Enterprise Elec. Co., this city, can identify these dates.

I am now going out to get our shop superintendents statement regarding the building and demonstrating of the butt and spot welder which was done on this machine in 1901. This gentleman is Superintendent of The Buckeye Traction Ditcher Co., in Findlay, O., at the present time, and after that I have one more statement to secure from one of the men now employeed by The Peerless Elec. Co., this city. These latter statements I will forward just as soon as I get them lined up, and will get them up in better shape if you think necessary. I have sent you copies only of the statements. I have the originals which are signed up by a Notary Public. If you can suggest anything to make these more water tight, kindly do so at your early convenience.

I have also samples of spot welding which was done on the welder at the time we did this experimenting, and while we are unable to identify the exact date, we can approximate it within two or three months.

There is one more thing about which I wish to advise you and that is: The idea of developing the butt welding machine was to enable us to manufacture a cheaper grade of fan than

the ones we were making at that time, and all fan motors of that desk fan type, had at that time brass blades and blade holders, or centers. Our idea was to make a steel blade and a steel center, and when we did that we proved out this electric spot welding process. These blades were to be painted or japanned black, and the guards were to be tin coated.

The company however were still manufacturing the high grade fans which necessitated brass blades and brass centers, and while we punched the blades with the same dies, it would have been necessary to have one set of dies arranged to punch the holes for rivets in the brass blades and another set of dies to punch holes for rivets in the blades and another set of dies without punches to make holes for rivets for the steel blades. This was considered at the time as being an objection as it necessitated added equipment which would not be necessary if we riveted all the blades, both brass and steel. We, however brass plated the steel blades after that time and found it took a very good finish, but Mr. Gillmer did not advocate the use of the spot welding of the steel blades, as we had already manufactured our punches, dies and had brass rivets in stock.

I feel that we have a particularly good case, and I want you to frankly criticise, and put it up to us in any way possible where we are liable to "stub our toes" on this, and when we finally get our evidence lined up, we want you to handle this deal with the Thompson Co., if you think we are in a position to offer to deal with them.

We have also heard from the "Toledo" Elec. Welder Co., and The "Windfield" Co., both of whom are very anxious to find out what I have in the way of information that can be used to advantage to them if they were able to get ahold of it and put up a fight against the "Thompson" Co.

The "Toledo" company are organized for $75,000.00 all paid in and good for this amount, but the "Winfield" company are not considered as being a good financial proposition at all.

Kindly advise what steps we are to take regarding the "Thompson" Co., and whether it is policy to hunt for business and promise our customers that we will be in a position to take care of them in case suit is entered against them or ourselves.

We would suggest that you secure a copy of the January 1913, issue of "Machinery" and look on page 182, you will see what the "Thompson" company have to say regarding the patent issued them recently.

In connection with the patent situation, Mr. Warren of the "Toledo" Co., has spent considerable money securing information regarding the various moves which have been made in securing the "Harmatta" patent, and he promised to forward the same to us, which would enable us to get copies.

Under the circumstances I told him we would be interested in securing this information, and when the same is forwarded to us we will be pleased to furnish you copies if you so desire.

Hoping we can get the matter straightened out in the near future, I am,

Very respectfully yours,
F. P. McBERTY,
Sec'y and Treas.
The National Elec. Welder Co.

The matter appearing in the 9th paragraph of this letter is confused and is corrected by letter of The National Electric Welder Co., dated February 10th, 1913, which reads as follows:

"Warren, Ohio. Feb'y 10th, 1913.

J. Nota McGill,
Attorney At Law,
Washington, D. C.

Dear Sir:— Re. yours Feb'y 7th, 1913.

We are enclosing herewith copy of paragraph as it should have read in our letter to you January 2nd, 1912.

'The company however were still manufacturing the high grade fans which necessitated brass blades and brass centers, and while we punched the blades with the same dies, it would have been necessary to have one set of dies arranged to punch holes for rivets in the brass blades and another set of dies without punches to make holes for rivets for the steel blades. This was considered at the time as being an objection, as it necessitated added equipment which would not be necessary if we riveted all the blades, both brass and steel. We however brass plated the steel blades after that time and found it took a very good finish, but Mr. Gillmer did not advocate the use of the spot welding of the steel blades, as we had already manufactured our punches dies and had brass rivets in stock.'

Regretting this typographical error we are,

Very respectfully yours,
THE NATIONAL ELEC. WELDER CO.
per
F. P. McBERTY,
Sec'y and Treas."

FPM/ZM

X-Q. 65. Will you please state what the notations are, in pencil, on page 2 of the letter of January 2nd, from Mr. McBerty just copied?

A. The first notation is an insertion of the name "J. W. Powers,'" after the word "gentleman" in line 4, the name being in the handwriting of the late J. Nota McGill. The second notation also in the handwriting of J. Nota McGill is the name "Robt. Bean"

inserted after the word "employed" in the 6th line of page 2. The paragraph in which these notations are made begins "I am now going out."

X-Q. 66. Will you please produce Mr. McGill's letter of February 7th, 1913, referred to in McBerty's letter of February 10th, 1913?

A. The letter of February 7th, 1913, referred to in the question appears at page 966 of Letter Book No. 50, and reads as follows:

"7th February, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

Please refer to your letter to me dated January 2, 1912. In the fourth paragraph page 2, lines 5 and 6, is there not some confusion? This reads:

'* * * for rivets in the brass blades and another set of dies to punch holes for rivets in the blades and another set of dies without punches to make holes for rivets for the steel blades.'

I wish you would throw a little light on this subject, and let me hear from you by early mail.

I have an engagement with Mr. Fish for Thursday of next week in New York.

Please look over the enclosed statement which I have prepared to hand Mr. Fish. Correct it wherever necessary. Please return it by early mail.

Very truly yours,
J. NOTA MCGILL.

Enclosure"

X-Q. 67. Have you the statement prepared for Mr. Fish referred to in this letter?

A. I have not.

X-Q. 68. Noted on the letter of February 10, 1913, to Mr. McBerty, in pencil, are the figures "2/11/13." Will you kindly produce the letter of that date evidently referred to by this notation?

A. The letter referred to by the pencil notation appears in Letter Book 51 at page 4, and reads as follows:

"11th February, 1913.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I have your letter of the 10th instant correcting the statement in your letter of January 2nd. I now understand that it was the purpose to make both the brass and steel blades with the same dies, but if the steel blades were spot-welded, holes would not be punched in them, hence they could not be made with the dies used for punching the brass blades since the lat-

ter had to have the holes made therein at the time of their formation.

I shall advise you as to the result of my conference with Mr. Fish.

Very truly yours,
J. NOTA MCGILL."

X-Q. 69. Referring to the letter of January 4th, 1913, on page 567 of Letter Book No. 50, will you please produce copy of the letter next preceding that from Mr. McGill to the National Electric Welder Co.

A. The letter relates to an interference and is in no sense in reference to this matter.

X-Q. 70. Will you please produce the next preceding letter?

A. The next preceding letter appears at page 375 of Letter Book 50 and reads as follows:

"13th December, 1912.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

Taylor vs. Warren.

I have received the concession of priority signed by Warren, but I have returned it for the corporate seal.

In thinking over the Harmatta patent, it occurs to me that it might be to your interests not to enter into any alliance with other manufacturers having for its object the making of terms with Thomson Co. If your evidence is, as it now appears to be, sufficient to invalidate the Harmatta patent, the Thomson people would doubtless be willing to negotiate with you on satisfactory terms, provided they were not compelled to similarly deal with your competitors. If there is any reason for giving the latter the benefit of the defense you have, then, of course, they will continue to be competitors. I suggest these things for your consideration.

Very truly yours,
J. NOTA MCGILL."

X-Q. 71. Referring to the letter of January 2, 1913, from Mr. McBerty to Mr. McGill, produced by you in answer to X-Q. 64, will you kindly produce the next preceding letter in order of time from Mr. BcBerty to Mr. McGill having any reference to the alleged spot welder by Mr. McBerty, at the Warren Company?

A. The next letter preceding that of January 2, 1913, from Mr. McBerty to Mr. McGill, relating to the spot welder matter, appears to be one dated December 9, 1912, which reads as follows:

"Warren, Ohio. December 9th, 1912.

J. Nota McGill.
Attorney At Law
Washington, D. C.
Dear Sir:—

We are returning herewith license signed up as per your request.

The writer has before him copy of the patent granted to the Thompson Co., but regret that I have not had an opportunity to look over the same carefully, as I just returned from a somewhat lengthy trip.

I expect to meet all parties interested in the manufacture of electric welding machines, excepting the Thompson Co., in Toledo, O. Wednesday of this week, and after that date I will be in a position to state definitely just what they expect to do, or think they can do regarding this patent situation.

In connection with this subject, I am interested in knowing whether if I manufactured a machine and did spot welding on it, before the application was made in England or the United States in a satisfactory; and practical manner, would this have bearing on the granting of the patent at the present date to the Thompson Co?

I have been looking up my witnesses and etc. on this matter and if we have any chance at all I am confident that we can either put up an extraordinary good fight, or be in a position to ask the Thompson Co., for a satisfactory settlement.

I will write you full details regarding the situation after my return from Toledo, Wednesday.

Thanking you for past courtesies, we are,

Very respectfully yours,
THE NATIONAL ELEC. WELDER CO.
per
F. P. McBERTY.
Sec'y and Treas.

FPM/ZM"

X-Q. 72. Will you kindly search the file again and tell me if there is any letter between December 9th, 1912 and January 2nd, 1913, from Mr. McBerty to Mr. McGill, having reference to this same subject matter?

I have searched the file and fail to find any such letter.

X-Q. 73. You fail to find any letter between those dates from Mr. McBerty to Mr. McGill having any reference to the subject of spot welding.

A. That is correct.

X-Q. 74. Will you please produce the letter from Mr. McGill to Mr. McBerty under date of December 10, 1912?

A. The letter referred to in the question appears in Letter Book 50 at page 351 and reads as follows:

"10th December, 1912.

The National Electric Co.,
Warren, Ohio.

Dear Sirs:

I have your favor of the 9th instant enclosing the license, which I have forwarded to the Toledo Electric Welder Co.

Yes, broadly speaking, if you constructed and operated a spot welding machine before Harmatta's first filed foreign application, and he is unable to show that the invention has been communicated by him to others in this country prior to the construction and operation of your machine, such machine will constitute an anticipation of Harmatta, provided it was not an abandoned experiment. In other words, if the machine was constructed and used in an experimental way and then abandoned, it will not be available as a defense. If, on the other hand, it was long in use, and was used where it could be seen by people connected with the establishment, it would constitute a good defense.

I note with satisfaction that you have been looking up your witnesses. Have you also looked up the machine? In other words, is it still in use?

I suggest that you be very careful in dealing with the Thomson Company. Take the matter up with me before dealing with them.

Very truly yours,
J. NOTA MCGILL."

X-Q. 75. Will you please produce the letter next succeeding the letter of December 10th, 1912, from Mr. McGill to Mr. McBerty, having reference to spot welding?

A. There is no letter between these dates relating to this subject, except the letter of December 13, 1912, which is already in the record.

X-Q. 76. Will you please produce the letter next preceding that of December 10, 1912, from Mr. McGill to Mr. McBerty, having reference to the matter of spot welding?

A. The letter next preceding that of December 10, 1912, appears at page 308 of Letter Book 50, and reads as follows:

"4th December, 1912.

The National Electric Welder Co.,
Warren, Ohio.

Dear Sirs:

I am sending you under separate cover, a copy of the Harmatta patent No. 1,046,066, which issued yesterday. The claims are apparently very broad.

Very truly yours,
J. NOTA MCGILL.

Copy enclosed."

X-Q. 77. Will you please produce the letter from Mr. McBerty to Mr. McGill, next preceding that of December 9th, 1912, having any reference to spot welding or electric welding?

A. The next preceding letter is one dated November 25, 1912, forwarding to Mr. McGill, copies of letters passing between The National Electric Welder Co. and Mr. Johann Harmatta, asking the latter with reference to his patent in the United States.

X-Q. 78. Is there any correspondence in your files on this subject in the years 1910 or 1911?

A. I find no such correspondence.

X-Q. 79. Is there any correspondence between January 1, 1912 and November, 1912, relating to the same subject matter?

A. I find a letter dated January 9, 1912, from The National Electric Welder Co. to Mr. J. Nota McGill which reads as follows:

"Warren, Ohio, 1-9-12.

Mr. J. Nota McGill,
Washington D. C.

Dear Sir:—

Some six weeks ago we requested Mr. Upton to secure for us copies of all patents relating to metal heating and working, and after having spoken to him about the matter a couple of times we have decided to take the matter up with your office, hoping to get more prompt attention to our requests.

We want to get in touch with what has been done in the electric welding line, with reference to welding machines both butt and spot welders, welding of rings, hollow ware, also anything in the arc welding which may be of interest.

We would ask that you kindly send us at your earliest possible convenience copies of these patents, together with bill for same.

We are now writing up two different matters to see whether we can get patents or not, and just as soon as we get these copies, if we find that we are not covering ground already gone over, we wish to take these matters up with you.

We regret to say that through some mistake of Mr. Upton's of getting the drawings signed for the lever switch, we have been unable as yet to get our patents issued.

Thanking you for your prompt attention, we are,

Very respectfully yours,
THE NATIONAL ELEC. WELDER CO.
Per
F. P. MCBERTY,
Treas.

FPM/Z"

Mr. McGill's answer to this letter is dater January 11, 1912 and appears at page 242 of Letter Book 47, and is merely advising of the number of copies of patents in those classes relating to welding and the cost of the copies. The letter will not be copied unless counsel shall request.

Cross-examination closed.

Mr. Church requests that the letter from Mr. McGill to Mr. Edwards, dated April 30, 1914, and referred to by the witness in his cross-examination be copied into the record, which is accordingly done, as follows:

"30th April 1914.

C. V. Edwards, Esq.,
2 Rector Street,
New York.

Dear Sir:

I thank you for your favor of the 27th instant, which I find upon my return to the city this morning. It seems to me that even if the answer did not lay foundation for evidence as to priority of invention, the court should have admitted it subject to an amendment to the answer, and anyhow ought to have allowed it under Zane vs. Soffe 110 U. S.

If printed briefs are used will you kindly let me have a copy.

Very truly yours,
J. NOTA MCGILL.

M.I."

Signature and Certificate Waived.

IN THE DISTRICT COURT OF THE UNITED STATES

EASTERN DISTRICT OF MICHIGAN

SOUTHERN DIVISION

IN EQUITY

THOMSON SPOT WELDER COMPANY

vs.

FORD MOTOR COMPANY.

Warren, Ohio, July 10, 1919, 3.30 P.M.

Pursuant to agreement of counsel.

Present: A. S. PATTISON, ESQ., Counsel for Defendant.
J. L. STACKPOLE, ESQ., Counsel for Plaintiff.

Deposition taken on behalf of defendant by agreement of counsel under the equity rules of the Supreme Court of the United States and under the Revised Statutes. Before me W. S. Helsley, Notary Public and Special Examiner.

WILLIAM B. ENSOR.

WILLIAM B. ENSOR, of lawful age, being by me first duly sworn to tell the truth, the whole truth and nothing but the truth, deposes and says as follows:

Direct examination by MR. PATTISON:

Question 1. Please state your name and age?

Answer. My name is William B. Ensor, age twenty-nine.

Q. 2. Where do you live?

A. Leavittsburg, Ohio.

Q. 3. What is your present employment?

A. I am in the service department of the Peerless Electric Company.

Q. 4. When did your employment begin there?

A. I began working for them January 1, 1911.

Q. 5. Have you during your employment with the Peerless Company seen a rivetless fan blade at that factory?

A. I did at one time.

Q. 6. Under what circumstances did you see it?

A. Shortly after I went to work for the Peerless Electric Company I was put in the experimental department developing a new line of one phase motors and we were looking for some resistance coils in the old stock house among a collection of old fans and repair parts and returned goods and so forth for these resistance coils. Mr. Kargeau and I went to the old stock house and I ran across an old Stanley Patterson fan that had a peculiar looking blade on it which attracted my attention to it because it did not have any rivets. I asked Kargeau what the thing was and he looked at it in an easy going sort of fashion and said he didn't know. We

looked it over and I asked him how he supposed the thing was fastened on there and he said he supposed some kind of welding proposition. I saw the fan and I looked it over very carefully, being young in the business I was very much interested in it, pretty much interested in any new thing that came around. I didn't seem to be able to get any particular interest roused up in Kargeau and I didn't pay much more attention to it.

Q. 7. Whose manufacture of fan was it?

A. The Warren Electric & Specialty Company. It was an older type than the Peerless Electric Company.

Q. 8. And Stanley Patterson Company, who are they?

A. They were the New York Agent, jobbers of the Peerless Electric Company, they sold for both concerns.

Q. 9. Are you sure that the blade referred to by you was a riveteless blade?

A. Oh, yes, no question about it. The blade was a black Japan blade and was perfectly smooth. My attention would not have been called to it if it had had rivets in it.

Q. 10. Where in the factory did you see the fan with the riveteless blade?

A. It was on the rack of repairs and returned stuff, this returned goods in what we now know as the stock room, there was a rack there on which returned goods were put that might be useful for repairs at some future date. These old fans are pretty valuable to us to get repair parts from.

Q. 11. Returned fans. Please explain what you mean by that.

A. Well, fans that have been returned as defective or returned for exchange, or replacement. So many times customers want to change them, find some minor defect with the fan and they return it to us.

Q. 12. Did you examine this fan sufficiently to see if it had been previously used?

A. Oh, it had been used. There was nothing put in that place except fans that had been used.

Q. 13. They had been out to the trade and came back?

A. No new fans were put in there. I suppose the average man would call it a junk room.

Q. 14. What was the condition of the blade when you examined it?

A. I didn't see anything wrong with it, didn't notice anything wrong with it.

Q. 15. Did the blades seem to be held securely in place?

A. Seemed to be all right so far as I noticed. Just an ordinary fan blade except it didn't have any rivets. I didn't see anything wrong with it.

Q. 16. When a fan is placed in the factory where you saw the one referred to what if anything does that location mean?

A. Well, it would mean it was an old fan, I suppose it would mean it had been out in service, no new stuff was put in there of

any kind and nothing has ever been put there that would be of recent manufacture, it would be an old fan.

Q. 17. What became of the fan, or the rivetless blade, if you know?

A. I don't know, it just disappeared.

Q. 18. Did you look for it at any time?

A. I have looked for it but I have been unable to find it. I noticed it out there on a few different occasions after that when I was looking for more repair parts but I couldn't say exactly what time it disappeared because I was taken off that work and put on the same work I am now engaged in, in other words, the engineering of service repairs and I was on that work for I think about a year, then I was put in the assembling department as foreman and during that period I knew nothing about repair parts aside from the ones that came in my own department and I lost all track of this old stuff that lay in the old stock house.

Q. 19. What is the custom of the Peerless Company if called upon for a fan blade of the older type that they were not manufacturing at the time the call came?

A. Well, if we can find one of them we ship it. On numerous occasions I have taken blades off of old fans, some that were down in our basement on obsolete fans. I have made a practice of removing repair parts from these and shipping them out, it is the only way you have to get these obsolete parts. We have so many different parts of fans and motors that we do not attempt to carry in our finished stock duplicates of all these old repair parts and once in a while it happens that we do have them in the junk pile that I have mentioned before or in some other department of the establishment, returned fans that are mechanically defective, or certain parts of them and we take these parts and refinish them and ship them out to the customer for repairs.

Q. 20. Do you know Mr. Newton Smith?

A. I have met him.

Q. 21. Please explain the circumstances.

A. He has been in our plant, we were looking for fans. I think I was with him on just one occasion. He was looking for an old type of fan.

Q. 22. Did he buy one?

A. Yes, I think Mr. Smith bought a fan.

(By Mr. Stackpole: Mr. Smith being present says he bought a Colonial fan.)

(By the Wintess: Mr. Smith was in and bought an old type fan. He was unable to get the fan with the Peerless name plate on it so he took one with the Colonial plate on it and knew it was made by the same company and in every way the same fan.)

Q. 23. Was anything said about this rivetless fan blade you had seen to Mr. Smith?

A. I mentioned to him having found the thing. Expressed regret that I was unable to locate it at the present time.

Q. 24. Have you any interest whatever in this question of spot welded fan or of the McBerty welder?

A. Not in the least.

Q. 25. Or of the result of this suit?

A. Not in the least.

Q. 26. Will you please give the full name of Kargeau to whom you have referred?

A. Theodore is his first name, he always wrote his name as T. Kargeau but Theodore is his name.

Q. 27. Do you know where he is now?

A. No, I do not, he went from here to Sarasota, Florida, he went on a fruit farm down there.

Q. 28. And that place in Florida you have referred to?

A. Sarasota.

Q. 29. How long since you heard from him?

A. Oh, I haven't heard from him for five years, I should say.

Q. 30. When did you meet me?

A. Yesterday.

Q. 31. Where?

A. Peerless Electric Company.

Q. 32. Who introduced me to you?

A. Mr. McBerty.

Cross-examination by MR. STACKPOLE:

X-Q. 33. Before you testified today were you shown Plaintiff's Exhibit Thirty-eight?

A. May I ask the counsel a question, if that is the same picture he showed me? It looks like the same picture, yes.

X-Q. 34. Are you sure?

A. Yes, that is the same picture I saw or one just exactly like it. That is a picture of the type G fan.

Re-direct examination by MR. PATTISON:

Re-D. Q. 35. When did I show you this picture?

A. About five minutes ago.

Re-D. Q. 36. In the other room just before you came in to testify?

A. Yes.

IN THE DISTRICT COURT OF THE UNITED STATES

EASTERN DISTRICT OF MICHIGAN

SOUTHERN DIVISION

THOMSON SPOT WELDER COMPANY

vs.

FORD MOTOR COMPANY.

Met pursuant to agreement of counsel.

Present: J. L. STACKPOLE, ESQ., counsel for plaintiff, and
A. S. PATTISON, ESQ., counsel for defendant.

Depositions taken on behalf of defendant under the Equity Rules of the Supreme Court of the United States, and under the Revised Statutes, before Carl D. Rice, Esq., Notary Public and Special Examiner, at Warren, Ohio, July 24, 1919.

JOHN B. ESTERBROOK.

JOHN B. ESTERBROOK, a witnessed called in behalf of the defendant, being first duly sworn, deposes as follows:

Direct examination by MR. PATTISON:

Question 1. What is your full name, and residence?

Answer. John B. Esterbrook, Warren, Ohio.

Q. 2. What is your present occupation?

A. Secretary and Treasurer of The Sun Light Electric Manufacturing Company.

Q. 3. How long have you been connected with that company?

A. Two years.

Q. 4. What was your occupation prior to your connection with the above mentioned company?

A. Secretary and salesman of The Peerless Electric Company.

Q. 5. Were you with the Peerless Electric Company in that capacity during the year 1913?

A. Yes, sir.

Q. 6. Are you acquainted with Mr. Fred P. McBerty of this city?

A. Yes, sir.

Q. 7. About how long have you known him?

A. I believe twenty-five (25) years.

Q. 8. While you were occupying that position with The Peerless Electric Company of this city, do you recall that Mr. McBerty came to that factory, the factory of that company, with another gentleman to make a search?

A. Yes, sir.

Q. 9. What, if you know, was the search for?

A. Mr. McBerty told me that he was looking for a spot welded fan blade.

(Mr. Stackpole: I object to the answer as hearsay.)

Q. 10. Was such search made?
A. Yes, sir.
Q. 11. Did you take any part in the search?
A. Yes, sir, I went over into the factory with them.
Q. 12. With Mr. McBerty and the other gentleman?
A. Yes, sir.
Q. 13. What did you search for?
A. I took Mr. McBerty and the other fellow into our room where we kept all of the obsolete fans and fan parts, and dug up for them all of these parts and completed blades that were there.
Q. 14. What were they looking for?
A. A spot-welded fan.

(Mr. Stackpole: I object to the answer as incompetent and hearsay.)

Q. 15. Did this other gentleman know what they were looking for?

(Mr. Stackpole: I object to the question as incompetent.)

A. Undoubtedly.
Q. 16. To what extent was the search made, as you remember?
A. We went through all the bins, and everything that was in that room, and dug up all the fan blades and fan parts that were there, and Mr. McBerty looked them over.
Q. 17. Did the search include that place where old fans would be placed that were returned from the trade, after having been on the market?
A. All obsolete types of fans were kept in that room, both fans that came back, and parts that had never been shipped out.
Q. 18. Can you state whether a spot-welded blade was found in this search?
A. Not to my knowledge.
Q. 19. State whether or not this search was the only occasion that you went with Mr. McBerty and another gentleman to look through the factory for old fans and fan blades?
A. That is the only search I helped make personally.
Q. 20. Do you recall the name of the gentleman that was with Mr. McBerty?
A. No, I do not.
Q. 21. State whether or not this search included more than one part of the factory?
A. It included this room I have described; it included the warehouse where there were some old fans; and it included the third story of the main building where there were some more fans.

(Mr. Pattison: That is all.)

Cross-examination by MR. STACKPOLE:

X-Q. 1. Was the other fellow with Mr. McBerty a lawyer, who was investigating the alleged spot-welding?

A. I can not tell you whether he was a lawyer or not. He was the man that came there with Mr. McBerty in the interest of this same proposition.

X-Q. 2. That was in the fall of 1913?

A. I would not say definitely in regard to that. I would say it was five (5) or six (6) years ago, in that neighborhood.

X-Q. 3. Was the other fellow's name Thomas Howe?

A. I don't know, sir.

X-Q. 4. In this search did you find any fans with steel blades?

A. Mr. McBerty inspected all of that stuff himself. I don't know what we dug up for him, I can not say.

(Mr. Stackpole: That is all.)

Certificate and signature waived by consent of counsel.

F. P. McBERTY.

F. P. McBERTY, a witness, who has previously testified in this case, being recalled in behalf of the defendant, testifies as follows in response to questions by MR. PATTISON:

Direct examination by MR. PATTISON:

Question 1. Are you the F. P. McBerty who testified in this case in Detroit before Judge Killitts, about some early spot welding that you did?

Answer. Yes, sir.

Q. 2. I believe you know Mr. Thomas Howe who has testified in behalf of the plaintiff in this case?

A. Yes, sir.

Q. 3. When did you meet him?

A. I met him in the fall of 1913.

Q. 4. What was the occasion of your meeting Mr. Howe?

A. Mr. Howe came to Warren to assist in collecting evidence in reference to the use of electric spot-welding machines.

Q. 5. What, in a general way, did Mr. Howe do in the way of investigating this question of spot-welding?

A. Mr. Howe went with me to different places to meet men formerly employed where the spot-welder was used. He also went with me to the plant of The Peerless Electric Company to assist in a search for any spot-welded fan blades we could locate.

Q. 6. You testified in this case at Detroit, and among other

things, you said, that you spot-welded a number of complete fan blades at The Warren Electric & Specialty Company, of Warren, Ohio, in 1901, which passed through that factory, and were put on completed electric desk fans that went out to the trade. Did you tell Mr. Howe about this when he was with you investigating the subject in 1913?

A. I did.

(Mr. Stackpole: This line of examination is objected to, if it is to impeach the testimony of this witness whose testimony has already been given.)

(Mr. Pattison: This witness has already testified that he had told Mr. Howe of these facts in 1913.)

Q. 7. What, if anything, was done by either you or Mr. Howe, or both, to obtain some tangible evidence of the making of the blades and putting them on completed fans that went to the market?

A. Mr. Howe and I went to the plant of The Peerless Electric Company, successors of The Warren Electric & Specialty Company, and made as detailed a search as we could possibly do, with a view of locating either a fan with spot-welded blades, that is a completed motor, and failing in that, to locate a spot-welded fan blade itself independent of the motor. This was done by going over the stock of old fans that had been sent out to the trade by The Warren Electric & Specialty Company and later returned for any reason whatever; and also by searching through numbers of trays which were filled with fan blades of various kinds and shapes that were in stock at the plant of The Peerless Electric Company, such fan blades being carried from year to year to replace blades that had been destroyed or lost.

Q. 8. Who was present during this search?

A. Mr. J. B. Esterbrook and Mr. Thomas Howe.

Q. 9. What was the reason for looking among the returned fans that had been out to the trade and come back to The Warren Electric & Specialty Company for some reason?

A. Mr. Esterbrook advised me that, in years prior to the date of this search, they had disposed of practically all the fans they had in the plant, and consequently any fan blades, or any blades that were spot-welded, would have gone out on the market; and our only chance of locating such a fan, he considered, would be found among the so-called second-hand or returned fans.

(Mr. Stackpole: I object to the answer as being hearsay.)

Q. 10. Did Mr. Howe understand the object of this search?

A. He certainly did.

Q. 16. Did he understand why you were looking among the second-hand or returned fans?

A. Yes, sir.

Q. 17. What did he understand about this?

(Mr. Stackpole: I object to the question as being incompetent.)

A. That was the only chance—That was our best chance to find a blade of this type—That our best chance to find a blade of this type would be to find it among some of the fans that had been sold by The Warren Electric & Specialty Company, and later on returned.

Q. 18. Was a spot-welded fan blade found on the occasion of this search?

A. No. We were unable to find any spot-welded fan.

Q. 19. What was Mr. Howe's attitude in respect to this matter?

(Mr. Stackpole: I object to the question as being incompetent.)

A. Mr. Howe's attitude was that it would be advantageous evidence if we could locate such a fan blade, as a positive demonstration of the prior use of spot-welding.

Q. 20. What were you endeavoring to establish for Mr. Howe, in making this search?

A. I wanted to prove to Mr. Howe that the fan blades had been spot-welded and sent out as a commercial product; and to secure sample of a completed specimen of a spot-welded blade, if possible.

Q. 21. You mean an original spot-welded blade that had been sent out to the trade and returned?

A. One of the original spot-welded blades that had been made in 1901, and had been sent out during that time, or about that time.

Q. 22. During your testimony in Detroit an affidavit was made by you in 1913, and drawn up by Mr. Howe, and offered in evidence on behalf of the plaintiff. State why, if you know, this affidavit makes no mention of the making of several spot-welded fan blades in 1901, which went through the factory and went out to the trade?

A. This affidavit, mentioned, was made to Mr. Howe after we had made a very thorough search for a completed blade that was welded in 1901. And Mr. Howe's suggestion was, that unless we had some positive, tangible evidence of such work having been done, that is, unless we could locate a blade and positively identify it as having been made at that time, it would be better policy to merely confine ourselves to a statement of the spot-welding done, and the sample we had, which was tangible.

Q. 23. You mean confine yourselves to the specimens that were attached to your affidavits?

A. Yes, attached to the affidavits already in hand.

Q. 24. If it had been that you did not tell Mr. Howe about

making a number of spot-welded fan blades, and sending them out to the trade, what possible reason could there have been for the search that you and he made at The Peerless Electric Company?

A. Absolutely no reason at all. The only desire was to locate a spot-welded fan blade.

Q. 25. What was the character of the interview that Mr. Howe had, in 1913, with Mr. John McDonald, who has testified for defendant in this case?

(Mr. Stackpole: I object to the question, as not calling for facts, and as being incompetent.)

A. His interview, so far as securing evidence in reference to this spot-welding, was very brief, and, in my judgment, unsatisfactory.

Q. 26. Did Mr. Howe on this visit ask Mr. McDonald to think the matter over and recall all that he possibly could, and that he would call to see him again?

A. No, he did not.

Q. 27. Did he, so far as you know, call upon Mr. McDonald again?

A. I never knew of his seeing Mr. McDonald other than that one time, until he saw him in Detroit recently.

Q. 28. About how much time was spent in this interview with John McDonald in 1913, in respect to this spot-welding proposition, and the electric welder?

A. The interview, in reference to the use of the electrical welder, and spot-welded blades, would not cover a period of more than three (3) to five (5) minutes all told. It was very brief.

Q. 29. What was Mr. McDonald's occupation at that time?

A. A farmer.

Q. 30. Was this an unexpected call on Mr. McDonald?

A. Yes, sir.

Q. 31. Had he been given any opportunity to try to recall or remember any of the facts about this spot-welding proposition?

A. No, sir, not at all.

Q. 32. I believe you are acquainted with John Gilder, who has testified in this case for the defendants?

A. Yes, sir.

Q. 33. Mr. Gilder and Mr. Howe have testified that Gilder was interviewed in 1913 by Mr. Howe in respect to this spot-welding proposition. Were you present during this interview?

A. I was present at one interview, to my knowledge.

Q. 34. About how long would you say that this interview lasted altogether?

A. My recollection would be, it lasted ten or fifteen minutes.

Q. 35. Had Mr. Gilder been given any previous opportunity to think about this early welding proposition before the interview?

A. Not to my knowledge.

Q. 36. When Mr. Howe was in Warren in 1913, investigating

this early spot-welding of yours, did you recall at that time that any catalogue of The Warren Electric & Specialty Company disclosed a fan with a spot-welded blade thereon?

A. No, I did not.

Q. 37. Did Mr. Howe suggest looking for any of the catalogues of The Warren Electric & Specialty Company, or The Peerless Electric Company, in this connection?

A. No, he did not.

Q. 38. Or about an examination of any other trade publications?

A. No, he did not.

Q. 39. How did you happen to discover The Warren Electric & Specialty Company's catalogue of 1901, with the illustrations of the G-2 fans, which you say are spot-welded?

A. This was brought about by request made by Mr. Pattison regarding catalogues and methods of advertising these fans and describing same.

Q. 40. Was there any search made in response to this request of Mr. Pattison's?

A. Yes. Immediately after the suggestion was made that there might be catalogues available, or at least it would be policy to search for such catalogues and descriptive matter, I went to the plant of The Peerless Electric Company, successors of the Warren Electric & Specialty Company, and asked their Mr. W. C. Ward, Manager of The Peerless Electric Company, whether there were any of the old catalogues still in existence illustrating the line of fans produced in 1900, 1901 and 1902.

Q. 41. What was the result of this search?

A. Mr. Ward very promptly advised me that such catalogues were in existence, and searching in the drawer of his desk, he handed me a 1901 catalogue, which gave a detailed description and cuts of the various types of fans manufactured by The Warren Electric & Specialty Company in 1901 and placed on the market at that time.

Q. 42. Were these catalogues available in 1913, when Mr. Howe was in Warren?

A. Yes, sir, they were.

(Mr. Pattison: Opposing counsel is asked whether any affidavits were called for during Mr. McBerty's testimony in Detroit, that he now wishes to be produced. If there are any in existence counsel for defendant will be very glad to produce them for opposing counsel.)

(Mr. Stackpole: The record will show whether any affidavits were asked for. The affidavits of Messrs. McBerty, Brown, Lipps, and others are already in the case, and seem sufficient.)

Q. 43. Are you acquainted with William B. Ensor, of Warren, Ohio.

A. Yes, sir.

Q. 44. Mr. Ensor has testified for the defendant in this case. When, and under what circumstances, did you meet Mr. Ensor?

A. I met him at the plant of The Peerless Electric Company recently, while making a search through the stock of old fans at the plant of The Peerless Electric Company.

Q. 45. What were you looking for?

A. I was endeavoring to locate a spot-welded fan blade on any returned fans that they might have in the factory or storehouse.

Q. 46. Did you find any?

A. No, I was not successful in finding any fan blade of that type.

Q. 47. What, if anything, did you learn at that time regarding spot-welded fans?

(Mr. Stackpole: I object to the question as calling for hearsay.)

A. I explained to Mr. Ensor the particular type of fan blade I was endeavoring to locate, and I was advised by him that, shortly after he became connected with The Peerless Electric Company, which was in 1911, that he saw such a fan blade on an old fan motor that had been returned; and owing to the peculiar construction of the blade, which was a blade without rivets, it attracted his attention; and he examined it quite thoroughly.

(Mr. Stackpole: What Mr. Ensor told the witness is objected to as hearsay.)

Q. 48. Were you the first one that Mr. Ensor told this to?

(Mr. Stackpole: I object to the question as incompetent.)

A. Mr. Ensor had taken this matter up also with the former chief engineer of The Peerless Electric Company.

(Mr. Stackpole: I object to the answer as being hearsay.)

Q. 49. What was his name?

A. Theodore Kargeau.

Q. 50. Did Mr. Ensor tell anyone else besides Kargeau before he told you?

A. I believe he also mentioned this matter to Mr. Hadly.

(Mr. Stackpole: I object to the answer as being hearsay.)

Q. 51. To anybody else?

A. Not to my knowledge. I made a misstatement right there.

Q. 52. If you have any correction to make in your answer, please do so.

A. He also told Newton A. Smith, the representative of The Thomson Spot Welder Company.

Q. 53. He told Mr. Smith before he told you?

(Mr. Stackpole: I object to the question on the ground it is incompetent and hearsay.)

A. He did.

Q. 54. During this occasion with Mr. Ensor, was an effort made to find this spot-welded blade?

A. Yes. After Mr. Ensor told me of this spot-welded blade that he had seen there, we made a very thorough search for it; thinking possibly it might still be at the plant of The Peerless Electric Company somewhere.

Q. 55. About when was this last search with Mr. Ensor, to which you referred?

A. In the month of June or July, 1919.

Q. 56. Have any efforts been made to locate Theodore Kargeau?

A. Yes, I have done practically everything I could to locate Mr. Kargeau. I telegraphed to the last known residence place of Mr. Kargeau, and I telegraphed to the postmaster at that town regarding his present whereabouts; and I have also telegraphed to parties who might possibly have some knowledge of his present whereabouts; but have been unable to locate him.

Q. 57. Mr. Thomas Howe, in answer to question 7, intimates that in 1913 he took to Warren a specimen spot-welded fan blade, that had reached Mr. Edwards through your attorney, Mr. McGill. Did he show you that specimen when he was investigating the question in 1913 in Warren?

A. Not to my knowledge.

Q. 58. Mr. Howe, in answer to question 11, gives the impression that you never told him of making more than one complete fan blade; and didn't tell him any spot-welded blades were assembled in complete desk fans that went out to the trade. Have you anything to say about this?

A. Mr. Howe's memory, in connection with this matter, is not good; as that was gone over very thoroughly, in detail the prior work that had been done on spot-welded blades. And his final judgment was, we should confine our testimony in reference to this spot-welding on actual samples we had on hand.

Q. 59. Mr. Howe says that when he was here in 1913, you didn't give him the name of William E. Smith as a former employee, who might know about the welder and work done on it. What is your recollection about that?

A. My impression in connection with this is, that we were at that time interested in workmen only connected with the fan motor department; and Mr. William E. Smith was directly connected with

the transformer department, and didn't get on the list of fan motor operators or producers, and was therefore overlooked.

Q. 60. About when, if you remember, and how, if you remember, did you learn that Mr. William E. Smith did know something about this spot-welding proposition?

A. This was brought to my attention, I think, two or three years ago, owing to the fact that some of the men I had talked with in connection with the spot-welding remembered that Mr. Smith had, at various times, worked in the fan motor department. And on inquiry of Mr. Smith, I found he was quite familiar with the entire process.

Q. 61. In answer to question 20, Mr. Howe says your welder in 1913 was incomplete in many respects. Have you anything to say about this?

A. The welder was complete in every detail, with the exception that I did not have the original spot-welder electrodes that I had used; and the machine was not mounted on a pedestal or base to permit its being operated. Otherwise, it was in the identical condition it is today.

Q. 62. Did Mr. Howe ask you to assemble the machine and operate it for him?

A. No, he did not.

Q. 63. Did he manifest any interest in seeing it operate?

A. No, he did not.

Q. 64. Mr. Gravell, a witness for the plaintiff, has testified in regard to the character of the spot welds on the fan blade that you spot-welded on your old machine at the Ford plant in the presence of Judge Killitts; and he calls attention to the fact that some of the welds on that exhibit (Defendant's Exhibit 56) stand obliquely in the metal. Have you anything to say in respect to this?

A. The demonstration, made at the plant of the Ford Company on this welder, was not made with a view of making as nice and as workmanlike a job as could be done; it was merely to demonstrate that the machine would spot-weld, and had ample capacity to do this work. And all that would have been necessary to make a perfect job would have been to dress up the points to the proper shape, and it would have made as satisfactory a weld as could be made with any spot-welder.

Q. 65. In spot-welding commercially, with the modern spot-welders of today, are all of the spots, of the series, which may be made on one piece of work exactly the same?

A. They are not. They vary, depending entirely on the amount of pressure applied, and the length of time the current is kept on.

Q. 66. What effect does the repeated use of the electrodes have on the appearance of the work?

A. The repeated use of the electrodes have a tendency to make it cup-shaped; has a tendency to press up around the outside edge of the electrodes, making a rougher weld.

Q. 67. Will the deepest part of the recess, made by the electrodes, be always in the center of the weld?

A. Not always. It depends entirely on how the work is held in position.

Q. 68. What is the result, in modern, commercial welding, spot-welding, so far as any oblique appearance of the welds is concerned?

A. The majority of the spot-welding work done has a projection on one side or the other of the welds, on the face of the sheets. The heat of the metal has a tendency to force up the metal around the welded point.

Q. 69. The witness Wagner for the plaintiff calls attention to the fact that The Warren Electric & Specialty Company's catalogue for 1901 (Defendant's Exhibit 2) does not describe that the blades of any of the fans are copper or nickel plate; but that it does state "other finishes if specified." What does "other finishes if specified" mean in this catalogue?

A. The standard finish on the high grade fans is brass, polished and lacquered; but the company stood at all times prepared to furnish copper-coated, oxidized, and nickel-plated fan blades, and other metal trimmings, upon request from the customer.

Q. 70. Mr. Edwards, a witness for the plaintiff, was attorney for the defendant in the Barney & Berry case, frequently referred to herein, and in answer to question 12 in this case, he gives the impression that it was at your initiative that he asked you in the Barney & Berry case, about your spot-welding, which you were not permitted to state at that trial. What have you to say about this?

A. Apparently Mr. Edwards' memory does not serve him well in this particular instance. I was telegraphed to to come to Boston immediately. In other words, urged to make haste. I went down there with a view of assisting them, by supplying any information available, but not with the intention or understanding I was to be called to the stand at all on that case, as I had not been prepared in any way, and knew nothing about how the case was to be handled.

Q. 71. How long prior to the trial was it you received this telegram—How long prior to the trial of The Barney & Berry case, was it you received this telegram?

A. My impression is that Mr. Frank Warren telegraphed to me on the last day of March, to be in Boston on the 1st day of April, or the following day, prepared to attend this case.

Q. 72. Did you request that you be called as a witness in The Barney & Berry case?

A. No.

Q. 73. Did you request that you be asked about your spot-welding in the Barney & Berry case?

A. No. I had no intention of being called to the stand.

Q. 74. Did you have anything with you at all relating to your prior spot-welding?

A. No.

Q. 75. In answer to question 11, Mr. Edwards says, that he had a conference with you, after the affidavits were obtained by Mr.

Howe, and that you told him (Mr. Edwards) that none of your spot-welded blades were put into use, or went out commercially. How about this?

A. I believe Mr. Edwards' memory fails him there again. I gave Mr. Edwards all the information I had given Mr. Howe, as well as what Mr. Howe had told him regarding prior use. And he also knew, I am quite confident, regarding our search for that spot-welded fan blade.

Q. 76. Did you tell him that the spot-welded fan blades were not adopted as a regular manufacturing proposition at The Warren Electric & Specialty Company's plant?

A. Yes, I told him that.

Q. 77. Plaintiff's witness, Curtiss Brewer, has testified in this case, in answer to question 50, that the fan blades, that The Warren Electric & Specialty Company used were received from an outside firm, with the rivet holes being punched. State what you know about this during the time you were with The Warren Electric & Specialty Company, including, as I understand it, up to the time that company sold out in 1902.

A. Mr. Brewer is mistaken in reference to that statement. As I, being in charge of the designing and construction of these fans, personally saw to it that dies were made for producing fan blades when we first started to manufacture fans. And from that time on, during my entire connection with The Warren Electric & Specialty Company, we stamped out all our own fan blades, both brass and steel. To my knowledge they never purchased blades at any time from outside sources.

Q. 78. In what form did the material come to the Warren Electric & Specialty Company, out of which the blades were stamped?

A. The brass came in sheets of the proper width to cut fan blades crosswise on the sheet, and in lengths from 6 to 10 feet long in boxes. And the steel came in boxes and bundles of the same general shape, straight sheets, from which to punch the blades.

Q. 79. The same witness, in answer to question 46, says, that the blades that the Warren Electric & Specialty Company used were of iron. State what you know about this, during the time that you were with the company.

A. Some of the blades produced in 1901, and later, were all of what we call cold-rolled, machinery steel. This sheet steel all the scale had been removed, and was smooth on the outer surface, and was reasonably soft. And this steel we used in stamping out the blades for the cheap fan.

Q. 80. Were any iron blades used by The Warren Electric & Specialty Company, as distinguished from the steel to which you have just referred?

A. Not to my knowledge.

Q. 81. What kind of spiders were used on the steel blades?

A. A steel spider was also used.

Q. 82. How were these made?

A. These were also punched out of sheet steel, but it was not as high-grade sheet steel, or with as fine a finish, as the material that the blades were produced from.

Q. 83. This same witness has testified, in answer to questions 22 to 24, that your welding machine was built on a block of fibre, about 8 by 10 inches, and about an inch thick. Was your machine mounted at any time on a block of fibre?

A. It was not.

Q. 84. Was your welding machine at any time mounted on a block, or anything, that substantially corresponds to the dimensions given by the witness?

A. After the machine was taken over by The Peerless Electric Company it was supplied with a base made of slate, which I would say, was about 8 by 10 inches by fifteen-sixteenths or seven-eighths inches thick. And this slate base was with the welding machine when it was purchased by myself in 1911 from The Peerless Electric Company, and is now with the machine in Detroit in custody of the Court.

Q. 85. Was your welding machine mounted on a block of fibre, or any other kind of block, as defined by Mr. Brewer, while it was owned by The Warren Electric & Specialty Company?

A. It was not.

Q. 86. The evidence in this case shows that when The Warren Electric & Specialty Company sold out its fan department to The Peerless Electric Company in 1902, this welding machine was moved over to another building in custody of The Peerless Electric Company. State whether this slate block, to which you have referred, was used with the machine before, or after, it was moved from The Warren Electric & Specialty Company?

A. It never was used with the machine before it was moved. How long afterwards, I don't know.

Q. 87. Do I understand from this, that your welding machine was mounted on a slate block or slab after it was moved to The Peerless Electric Company in 1902?

A. Yes, it was.

Q. 88. As I understand your testimony, given in this case, the spot-welding of blades all occurred on this machine while it was with The Warren Electric & Specialty Company?

A. All done in the early part of 1901, while at the plant of The Warren Electric & Specialty Company.

Q. 89. How was your welding machine mounted at The Warren Electric & Specialty Company, prior to putting it on the slate base at The Peerless Electric Company?

A. It was built to the top of a hard-wood bench, with the bed of 2 angle irons extending out from the edge of the bench some distance.

Q. 90. State whether or not its mounting at The Warren Electric & Specialty Company is correctly represented in its present mounting in this case?

A. As near as we could duplicate the original conditions.

(Mr. Pattison: The direct examination is closed.)

Cross-examination by MR. STACKPOLE:

X-Q. 1. You say that the slate base of your welder is with the machine now in Detroit, in the same box with the machine?

A. It is my impression it is in a smaller box, which is down inside of the crate.

X-Q. 2. And that is a slab of slate 8 by 10 inches?

A. Approximately so.

X-Q. 3. And about ⅞ of an inch, or thereabouts, thick?

A. Yes.

X-Q. 4. Is the slate base cut, or carved, or plain?

A. It has a hole in the center to permit the bed of the welder to extend down through.

X-Q. 5. How big is that hole?

A. I would say it is 2½ by 8 inches.

X-Q. 6. How can you get a hole that size in a plate 8 by 10?

A. You can drill it in, or saw it in, or any other way. You have still an inch of material at each end, and considerable material out on each side.

X-Q. 7. What is the object in using slate?

A. That, I think, was done to conform to more rigid electrical specifications, which had gone into effect in the installation of electrical apparatus in later years.

X-Q. 8. What became of the specimen you say you showed Mr. Fish at the time of the trial of the Barney & Berry case?

A. That was later on turned over to Mr. J. N. McGill, and, as I understand, was in turn given to Messrs. Edwards, Sager & Wooster.

X-Q. 9. You say you showed this to Mr. Fish at the time of the Barney & Berry case, was that about March or April 1914, or 1915?

A. That was 1914. My interview with Mr. Fish, I think, was the late fall of 1912, or the early spring of 1913.

X-Q. 10. While you were recently making a search with Mr. Ensor in The Peerless Company's plant for fans, did you find any G-1 or G-2 fans?

A. I do not believe we found any of the original G-1 or G-2 fans.

X-Q. 11. What became of the statement that Mr. McDonald gave you in 1913, or thereabouts?

A. That is something that I cannot answer definitely; but my impression is that it is still among the correspondence of The National Electric Welder Company. As this statement was left at our office for Mr. McDonald to call for and sign. But he never did.

X-Q. 12. In your search in The Peerless Company's plant in 1913, did you find any G-1 or G-2 fans?

A. Yes, we found several of those old fans at that time.

X-Q. 13. So far as you know, they have since disappeared?

A. Yes, they have all been disposed of in one way or another.

X-Q. 14. Did both the old G-1 and G-2 fans have steel spiders?

A. Yes. the regular product did.

X-Q. 15. And these steel spiders were they the same shape?

A. The same shape, and the same size in both the 12 and 16 inch fans.

(Mr. Stackpole: That is all.)

Re-direct examination by MR. PATTISON:

Re-D. Q. 1. Were you asked by any one in connection with The Barney & Berry case to have your machine ready to demonstrate its operation for that case?

A. No, sir. I was not.

Re-D. Q. 2. I will ask you to state whether the G-1 fan, in the 1901 catalogue, shows a fan blade of the standard construction for that type of fan?

A. No. I would say that it did not, as the fan blade shows three (3) rivets per blade, which would indicate it had a brass center. This would not be standard production for that type and grade of fan.

Re-D. Q. 3. What is the standard production for that type and grade of fan?

A. A steel blade, with a steel center, and two (2) rivets per blade.

Re-D. Q. 4. How are these two (2) rivets located?

A. The two (2) rivets are located centrally on the blade, and about 2¼ inches apart.

Re-D. Q. 5. How were they arranged in respect to the blade, transversely, or longitudinally.

A. Longitudinally.

Re-D. Q. 6. State what kind of blade is illustrated on the G-2 type of fan in the 1901 catalogue?

A. That is a spot-welded blade, steel, with a steel center,

Re-D. Q. 7. What is the shape of the center of that blade?

A. The center has four (4) arms, attached to the steel hub, with the arms extending out from the center, and slightly tapering out to the outer end, that is more so than they are closer to the hub.

Re-D. Q. 8. State whether the spider of the blade in the cut G-2, in the 1901 catalogue, is the same shape as the spider of the fan blade which you spot-welded at the Ford plant in the presence of Judge Killitts, which I think is Defendant's Exhibit 56?

A. The spider would be the same shape identically.

Re-D. Q. 9. Is it the same size, or a different size?

A. The same size

Re-D. Q. 10. Do you mean by this that the same size steel spider was used for the G-2 and G-1 type fans?

A. Yes, it was. Never had but the one size die for stamping out steel spiders.

(Mr. Pattison: That is all.)

Re-cross-examination by MR. STACKPOLE:

Re-X-Q. 1. Besides the cut of G-2, found in the 1901 catalogue, have you any other evidence of the shape of the steel spider used in these G fans?

A. Yes, we have. The Peerless Electric Company are still using the original dies made at that time.

Re-X-Q. 2. Have you any other evidence than your recollection?

A. Samples of the spot-welding, which I have submitted in connection with my affidavit.

Re-X-Q. 3. Anything else.

A. That is all I have, to my recollection.

Re-X-Q. 4. The cuts of these fans, G-1 and G-2, bear the name "Manz, Chicago." Were the fans themselves sent to Manz of Chicago to be photographed?

A. That is something I cannot say. Sometimes we sent them out, and sometimes we had a local photographer take them.

Re-X-Q. 5. If Manz at Chicago took the photographs, would you say that the fans were sent to Chicago, or not?

A. If Manz took the photographs, I would say yes. But that mark on there indicates that Manz made the cuts, and does not indicate that he made the photographs at all.

Re- X-Q. 6. Do you know who did make the photographs?

A. I am not in a position to say.

Re-X-Q. 7. Do you know whether the photographing of the fans for this catalogue was done as one job, or some at a subsequent time or not?

A. No. I would not want to make a definite statement on that either.

(Mr. Stackpole: That is all.)

Re-direct examination by MR. PATTISON:

Re-D. Q. State whether or not Defendant's Exhibit M, which was offered during your testimony in Detroit, with your name and date on it, contains a spider of the same size and material as would be in the blade of the G-2 fan in the 1901 catalogue?

A. It does.

(Mr. Pattison: That is all.)

(Certificate and signature waived, by consent of counsel.)

(Mr. Stackpole: No cross-examination.)

Certificate and signature waived by consent of counsel.

MRS. ZELLA A. MCBERTY.

MRS. ZELLA A. MCBERTY, a witness called on behalf of defendant, having been duly sworn, testifies as follows in answer to questions by Mr. Pattison:

Direct examination by MR. PATTISON:

Question 1. Please state your name and residence.

Answer. Zella A. McBerty, 29 Washington Avenue, Warren, Ohio.

Q. 2. What is your present occupation?

A. Secretary and Treasurer of The Federal Machine and Welder Company.

Q. 3. What was your occupation prior to your connection with The Federal Machine & Welder Company?

A. Assistant Secretary and Treasurer of The National Electric Welder Company.

Q. 4. While you were with the National Company, was a Mr. Newton Smith in the employ of that company?

A. Yes.

Q. 5. What was his employment there?

A. Shop Superintendent.

Q. 6. Approximately, how long was he with The National Electric Welder Company?

A. I can not say definitely as to the exact dates; but he came in the winter and left in the early spring of 1917.

Q. 7. Did his employment cease there while you were with that company?

A. Yes.

Q. 8. What was the reason of his leaving the company?

A. Well, I would say, because he was not satisfactory.

Q. 9. Was there any complaints about him from anyone in the office of the company?

A. Yes. One of my stenographers made complaint to me that he made himself rather obnoxious, in looking over letters which she was writing, and correspondence that was laid on her desk that she was to answer for Mr. McBerty.

Q. 10. Was he caught spying around the plant?

A. I noticed Mr. Smith a couple of times looking over the mail on Mr. McBerty's desk.

Q. 11. Did you catch him at any time other than these?

A. One time at the safe. I hadn't locked it up, and I came back in the office after working hours, and he was at the safe, and had opened up the doors. And he said to me, when I came in, "You have forgotten to lock the safe." I said, "I notice I did."

Q. 12. What was the reason for this spying of Mr. Smith's in the National Company, if you know?

A. He was in the employ of The Thomson Spot-Welder Company.

Q. 13. State, if you know, what he was trying to find out at The National Company?

A. As much as I can say, he was trying to see if we had spot-welders that were not under the lease and license arrangement with The Thomson Spot-Welder Company, as per agreement with The National Company. I don't know of any other reasons, although I presume there were several, but that would be the most important to my mind.

Q. 14. Did he leave himself, or was he discharged?

A. I think he handed in his resignation to Mr. McBerty.

Q. 15. At the time he left did you regard him as a spy, sent to your place?

A. I would not say that I did. Because he had told us, when he came into our employ, that he had no connection, and knew nothing of The Thomson Spot Welder Company.

Q. 16. Were you suspicious of him prior to the time you found him in the safe?

A. No, I would not say I was. Although we certainly criticised his work, and thought there was something radically wrong, because our production was not up to standard, and we were endeavoring all we could to help it, and he did not seem to want to help as we thought he should.

Q. 17. How did you happen to find him in the safe?

A. Well, one of the girls in the office had remarked that she thought it peculiar that Mr. Smith knew the combination of the safe, as she thought I was the only one that did. She said, that one morning, I was late, and they wanted to get into the safe, and he and Mr. Johnstone, who was at that time in our employ, opened up the safe; either Mr. Smith or Mr. Johnstone, I can't say which. Then after these various things had come up, his looking at the correspondence, and such things, I was a little bit suspicious.

Q. 18. How was it that you came back to the place, after leaving the office, and found Mr. Smith in the safe?

A. Because I wanted to see what he would do under those conditions.

Q. 19 Under what conditions?

A. I had left the safe unlocked, and I said I would take the mail sack down, which was not customary; and I drove out a little ways, and turned around and came back, and went into the office quietly, and he was at the safe, and had opened the doors.

Q. 20. Did you leave the doors of the safe closed when you left?

A. Closed, but not locked.

Q. 21. When you came back you found him there with the doors open?

A. Yes, sir.

(Mr. Pattison: That is all.)

(Mr. Stackpole: I have no cross-examination. The entire deposition is objected to as being irrelevant and immaterial, and is not sur-rebuttal.)

Certificate and signature is waived by consent of counsel.

JOHN S. GILDER.

JOHN S. GILDER, a witness, who has heretofore testified in this case on behalf of the defendant, testifies as follows in answer to questions by Mr. Pattison:

Direct examination by MR. PATTISON:

Question 1. You are the John S. Gilder who testified in this case at Detroit?

Answer. Yes, sir.

Q. 2. At Detroit you testified about doing butt-welding on the McBerty welder at the factory of The Warren Electric & Specialty Company in 1901?

A. Yes, sir.

Q. 3. At the time you did this welding, state whether or not the welder was mounted on a fiber block or slab of any kind?

A. No, sir. I don't remember of anything of that kind. As I remember it was mounted right on the bench.

(Mr. Pattison: That is all.)

(Mr. Stackpole: No cross-examination.)

Certificate and signature waived by consent of counsel.

EDWARD L. BETTEKER.

EDWARD L. BETTEKER, a witness called on behalf of the defendant, having been first duly sworn, testifies as follows in answer to questions by Mr. Pattison:

Direct examination by MR. PATTISON:

Question 1. What is your name and residence?

Answer. Edward I. Betteker, Warren Township.

Q. 2. What is your present occupation?

A. Farming.

Q. 3. Were you ever employed by The Warren Electric & Specialty Company?

A. Yes, sir.

Q. 4. What was your employment there?

A. Press work, and so on.

Q. 5. Were you familiar, during your employment by The Warrent Electric & Specialty Company, with the manner of making their fan blades?

A. Well, I punched out the fan blades, I guess all that were made, that is, until they got more presses, then I supervised the work.

Q. 6. Out of what material were those fan blades made?

A. Brass, and cold-rolled sheet steel.

Q. 7. What was the color of this cold-rolled steel?

A. Well, it was bright steel, no scales, or anything like that on it.

Q. 8. Were you employed by The Warren Electric & Specialty Company at the time they sold out to The Peerless Electric Company?

A. Yes.

Q. 9. When did your employment begin with The Warren Electric & Specialty Company?

A. 1899, I believe, the day after Christmas, the 26th of December.

Q. 10. In what form did the material come to The Warren Electric & Specialty Company, the material out of which the fan blades were made?

A. Came in boxes, probably 10 or 12 feet long, in strips. Some of the strips, I believe, were 6 inches wide, for the 12-inch fan, and the other was perhaps 8 inches wide. It might have been less, but that was about the size of it.

Q. 11. State whether this material came through your department?

A. Yes. I got it from the stock room, to put through the press department.

Q. 12. Who did the press cutting of these fan blades during the years 1901 and 1902?

A. I probably did it myself at that time. I think it was about 1903 when we got more presses in there, and I didn't do so much press work myself then.

Q. 13. Did you do all the blade cutting up to 1903, when you got more presses?

A. Yes.

Q. 14. In cutting out these brass and steel blades, when the blank was first cut, was it with, or without rivet holes?

A. Without rivet holes.

Q. 15. Then the blank blade would have to have rivet holes punched through it?

A. Yes, in another operation.

Q. 16. Is it correct to say that you had one set of dies to punch out the blank blades, and another set to punch out the rivet holes?

A. Yes.

Q. 17. These two punching operations were separate operations?

A. Oh, yes.

Q. 18. Mr. Curtiss Brewer has testified in this case, that in 1901 The Warren Electric & Specialty Company bought its fan blades from an outside firm. Do you agree with that statement?

A. I never knew it, if they did.

Q. 19. In 1901, I understood you to say, that you cut out the blades that were used there?

A. I was there from 1899, and I cut them out until 1903. I did all the punch work. We only had one press, with the exception of a foot press. I think in 1903 we got more presses, and then I supervised the work.

Q. 20. And the blades were made out of this bright, cold-rolled steel?

A. Yes.

(Mr. Pattison: That is all.)

Cross-examination by MR. STACKPOLE:

X-Q. 1. Did you at that time punch the brass blades with the same dies as you punched the steel blades?

A. Yes.

X-Q. 2. The dies were the same?

A. Yes.

X-Q. 3. And the holes were punched with the same dies?

A. Yes. We had one set for punching holes, and one set for blanking—One set for the 16-inch fan, and one set for the 12-inch fan.

(Mr. Stackpole: That is all.)

Re-direct examination by MR. PATTISON:

Re-D. Q. 1. What kind of centers were used with the steel blades?

A. I think we punched that out of 14 gauge steel.

Re-D. Q. 2. How many rivets did that have?

A. Had 8 holes; two holes in an arm, and a hole in the center.

Re-D. Q. 3. Were there any fan blade centers, made by The Warren Electric & Specialty Company, that had different steel centers?

A. They were the same.

Re-D. Q. 4. How about the brass centers?

A. They were the same; unless the first ones we made had three holes, that was the only change. I am speaking about the two (2) hole blades.

Re-D. Q. 5. Then you had a different die for the spiders that had three (3) holes?

A. No. The spider that had three (3) holes was the one we used for the first two or three years; and then we changed over to an iron spider having eight (8) holes, two (2) in each arm, and one in the center.

Re-D. Q. 6. In the steel spider you had two (2) rivet holes?
A. Yes.

(Mr. Pattison: That is all.)

(Mr. Stackpole: That is all.)

Certificate and signature waived by consent of counsel.

(Mr. Pattison: Notice is hereby given that the record and briefs used in the Court of Appeals, in The Barney & Berry suit, will be handed to the Court, and referred to by defendant at the hearing.)

Adjourned to Findlay, Ohio, at the office of Messrs. Snyder & VanCampin, at 11 o'clock A.M., July 25, 1919.

IN THE DISTRICT COURT OF THE UNITED STATES

EASTERN DISTRICT OF MICHIGAN, SOUTHERN DIVISION

No. ———.

THOMSON SPOT WELDER COMPANY, Plaintiff,

vs.

FORD MOTOR COMPANY, Defendant.

Pursuant to agreement, counsel met at Findlay, Ohio, July 25, 1919.

Present: J. L. STACKPOLE, of counsel for plaintiff, and
A. S. PATTISON, counsel for defendant.

JASPER W. POWERS.

JASPER W. POWERS, a witness called on behalf of the defendant, having been duly sworn in this case, testified as follows:

Direct examination by MR. PATTISON:

Question 1. Please state your name and residence.
Answer. Jasper W. Powers: Findlay, Ohio.
Q. 2. What is your present employment?
A. Superintendent of the Star Tractor Company.
Q. 3. Are you the Jasper W. Powers who testified in this case at Detroit before Judge Killitts?

A. I am.

Q. 4. At Detroit you testified about making parts of an electric welding machine, testified to by Mr. McBerty. I supposed you had been asked about all the work you did on that machine, but on examining the record I have failed to find that you testified whether you had any knowledge about the electrodes that were said to be used in that machine. Did you have any such knowledge?

A. I did.

Q. 5. What do you know about the making of electrodes for use in that machine?

A. Are you speaking of the blocks that—you mean the electrodes that were used in the spot welding?

Q. 6. Yes.

A. I made one or more pairs.

Q. 7. What was the shape of these electrodes?

A. They were round copper wire, what we would call hard-drawn copper wire.

Q. 8. How thick?—by Mr. Stackpole.

A. It was heavier than a quarter inch, and as I remember, it was about five-sixteenths.

Q. 9. How about the ends of these?

A. To describe that more fully, I will say it was larger than a fan guard rim or ring.

Q. 10. How about the shape of the ends of these electrodes?

A. They were slightly pointed, conical shaped.

Q. 11. When, as you remember, did you make these electrodes in reference to the time you did the work on the machine?

A. It was along about the same time; it was after the machine was in operation on butt welding.

Q. 12. You also testified to a conference between yourself and Mr. McBerty and Mr. Gillmer to determine whether the spot-welded blade should be adopted in place of riveted. State whether you did the work on these electrodes after or before this conference?

A. The work on the electrodes was before the conference.

Q. 13. Have you any reason for stating why these electrodes were made before the conference to which you refer?

A. At the time we did the spot welding, and considered using it as a manufacturing process for that season, or on that fan, I had a great many parts made up and all my fixtures were made for riveted blades. I don't know that I recall clearly anything else in connection with it except the early season, the early part of the season was when we were getting our parts out and I had those parts all made up, and argued in the conference against using the spot-welding.

Q. 14. You mean this argument occurred early in the season of 1901?

A. Yes.

Q. 15. And it was before this time that you made the electrodes to which you referred?
A. It was.

Cross-examination by MR. STACKPOLE:

X-Q. 16. You remember making any bent electrodes?
A. I do not.

Signature and certificate waived by agreement of counsel.

DISTRICT COURT OF THE UNITED STATES

EASTERN DISTRICT OF MICHIGAN.

SOUTHERN DIVISION

Harmatta Patent No. 1,046,066.

In Equity, No. ———

THOMPSON SPOT WELDER COMPANY, *Plaintiff*,
vs.
FORD MOTOR COMPANY, Defendant.

Evidence taken on behalf of the defendant under the Revised Statutes of the United States and the Equity Rules of the Supreme Court of the United States, in accordance with stipulations heretofore entered into by counsel for the respective parties and pursuant to the annexed notice, before me, the undersigned Notary Public in and for the County of Wayne, State of Michigan.

EDWARD T. JEAN,
(Seal) *Notary Public.*
My Commission expires March 31, 1923.

The parties met pursuant to the annexed notice at the office of Messrs. Barthel, Flanders & Barthel, 408-414 Buhl Block, 35 W. Congress Street, Detroit, Michigan, on the 24th day of July, 1919, at 10 o'clock A. M.

Present: Otto F. Barthel, of counsel for defendant.
William S. McDowell, of counsel for plaintiff, specially appearing for plaintiff for purpose of making objections to be hereafter stated.

It is stipulated that for convenience of counsel and the witnesses to be examined, the taking of testimony herein is adjourned to the office of O. J. Beaudette and Company, Pontiac, Michigan.

Parties met at the office of O. J. Beaudette and Co., Pontiac, Michigan. Present, as before, and the taking of testimony was commenced at 2.30 o'clock P. M., July 24th, 1919.

(William S. McDowell, associated with Stevenson, Carpenter, Butzel & Backus, attorneys for plaintiff, object to the taking of the testimony at this time for the reason that J. L. Stackpole of Boston, attorney in charge of this case for the plaintiff is this day engaged in the taking of the testimony in the same matter at the office of the Federal Electric Welding Company at Warren, Ohio, on the part of the plaintiff and that local counsel have not sufficient knowledge of the issues involved to properly conduct cross examination. Further, counsel for plaintiff objects that the taking of testimony at this time is improper, and should not be considered by reason of the fact that plaintiff's testimony is being taken simultaneously at Warren, Ohio, in said cause, and by reason thereof plaintiff cannot be represented at the hearing now about to be had. Counsel for plaintiff therefore moves that any testimony taken during the time that the testimony is being taken at another place in the same case should not be received as a part of the record in this case.)

(By Mr. Barthel: In view of the fact that it is my understanding that this case is set for trial July 31st, and as the time is drawing to a close in which to put in defendant's proof, it is necessary to take the testimony of these witnesses at this time, and the further fact that complainant has been represented in this cause by at least three or four different counsel who have conducted the examination of witnesses, it is not seen why it is particularly necessary that Mr. Stackpole should examine these witnesses.)

(Counsel for defendant gives notice on the record that in addition to the witnesses named he will examine:

Frank E. Mills, Assistant Manager of O. J. Beaudette and Co., Pontiac, Michigan.

M. L. Evely, Superintendent of O. J. Beaudette and Co., Pontiac Michigan.

A. W. Neeland, and J. G. Wright, both employes of O. J. Beaudette and Co., Pontiac, Michigan.)

A. W. Neeland.

A. W. Neeland, being duly sworn, deposes and says in answer to interrogatories propounded to him by Mr. O. F. Barthel, as follows, to wit:

Direct examination.

Question 1. What is your name, age, residence and occupation?

Answer. Andrew Winton Neeland; age 32; residence 262 South Paddock Avenue, Pontiac, Mich.; occupation, spot welder.

Q. 2. Where are you occupied as spot welder?

A. At the O. J. Beaudette Body Company, Pontiac Mich.

Q. 3. What kind of spot welding work do you do?

A. Most of it is on touring car rear seats; occasionally on other work—roadsters.

Q. 4. How long have you been engaged in this spot welding work?

A. Since October—1912.

Q. 5. How do you fix this date of October, 1912?

A. That is the time I first began welding; first welding I ever did, and I came here to do that work; promised to do that work when I came in. I had worked here previous to that time, but the shop shut down and I went to my old home, and every year they have a celebration on the Saturday nearest the 24th of August—and I came back directly after that, the Monday following, I came to the shop and they were not ready to start yet, so I went out on the farm and worked six weeks.

Q. 6. And was it immediately after that you started your work with the O. J. Beaudette and Company?

A. Yes—they sent for me while I was there.

Q. 7. For what car was this welding work done of which you speak?

A. For touring car.

Q. 8. Was that work which you did in October, 1912, for Ford touring cars?

A. Yes.

Q. 9. About how many of these per day were made when you started in October 1912?

A. We made about fifty per day for the first, probably ten days. Had some trouble getting fifty for the first day or two.

Q. 10. And about how many did you run your production up to within say the first thirty days?

A. Probably three hundred a day.

Q. 11. How were these spot welded?

A. Well, the seat was pressed in five pieces with a bead on each seat, and these beads were lapped over and the welds placed between two and three inches apart—along the bead.

Q. 12. How were these welds made?

A. The seat was placed back up on a post and welding was made by bringing the top die down on the work.

Q. 13. By post and die, do you mean contacts, or electrodes?

A. Yes.

Q. 14. About what time in October do you estimate that you started to work?

A. Probably the tenth; wouldn't be far from the tenth.

Q. 15. How were you paid for this work at this time?

A. Was paid by the day—for the first four or five weeks or maybe six weeks—don't just remember.

Q. 16. How were you paid after that?

A. By the piece.

Q. 17. What determined the change in rate of pay?

A. Production.

Q. 18. That is, when production got up to a certain amount, you changed from day work to piece work?

A. Yes.

Q. 19. The spot welders were set up in the shop ready for use when you came here?

A. One.

Q. 20. You have been working for O. J. Beaudette & Co from the time you started in October, 1912, up to the present time?

A. Nearly all the time. Last summer I was off for about four months. They were not putting out any touring cars then. They shut down about the middle of August and do not know just when they started touring cars again but they were running them again when I came back in the middle of December. You understand I worked for them before I began spot welding. The first work I did was in April, 1911—the summer of 1912 I was away.

Q. 21. And this is how you remember that you started to do spot welding in October, 1912—is that it?

A. You asked me if I had been here ever since 1912, and I said I had worked here before that.

Q. 22. But do you remember positively that you started to do spot welding on Ford bodies in October, 1912?

A. Yes, as I stated.

Cross-examination by MR. MCDOWELL:

(Having objected to the taking of this deposition, reserve whatever right of examination we may have to such further time as may be determined.)

Signature waived by consent of counsel.

J. G. WRIGHT.

J. G. WRIGHT, being duly sworn, deposes and says in answer to interrogatories propounded to him by MR. BARTHEL, as follows, to wit:

Direct Examination.

Question 1. What is your name, age, residence and occupation?
Answer. James Gilbert Wright; age 45; residence 45 Henderson

Ave., Pontiac, Mich.; occupation spot welder, O. J. Beaudette & Co., Pontiac, Mich.

Q. 2. Where are you engaged as spot welder?

A. O. J. Beaudette & Co., Pontiac, Mich.

Q. 3. How long have you been in their employ?

A. Ten years—came the last of May, along about the 20th of the year 1909. Am not sure about the exact day.

Q. 4. How long have you been doing spot welding?

A. Since October, 1912.

Q. 5. What kind of spot welding work was this that you did in 1912?

A. Ford touring car. Rear seats; also some town car tops.

Q. 6. How did you happen to be doing this work at the plant of O. J. Beaudette & Co., Pontiac, Mich., at this time?

A. I had been here for two years, or something like that. Had been on the beader, and we made seats all in one piece, and then a change was made and they were pressed out into five pieces. Thru the summer I had been in New York State until the latter part of June. There were five or six of us making up bending strips all summer. I was one of the oldest men in the metal room, so when they got spot welders they did away with the order job and so I was changed immediately to the spot welding job.

Q. 7. How long before October, 1912, did you see these spot welders at the plant of O. J. Beaudette & Co., Pontiac, Mich.

A. I cannot say. I remember when the first one was there. It stood by the door quite a little while, then they moved it down near where the water fountain is now, and it stayed there, and then it was set up and used for welding town car tops. Then I think Mr. Buffington was there for a week or two welding town car tops, and then when they got the presses in shape. Mr. Neeland came in, and they put us on spot welding. This was sometime in October.

Q. 8. And have you been doing spot welding work ever since on Ford car bodies and tops?

A. Yes. Except sixteen days last summer.

Q. 9. Were these bodies the regulation Ford commercial automobile bodies?

A. They were.

Q. 10. That is, the touring car bodies?

A. Yes—and roadster bodies also.

Q. 11. About how many of these per day were gotten out by you and Mr. Neeland during October, 1912?

A. Well, that is pretty hard to say. We started in somewhere about fifty (50) and of course increased as fast as we could. It was right around Fall, just before election, that Mr. MacGuire sent me after a gentleman by the name of Mr. Viola who is working here at the present time, and it was just about two weeks after he came that we started on two machines, and we had had one machine in operation I should say nearly a month.

Q. 12. How many a day did you get out when they got the second machine?

A. Right around 300.

Q. 13. How were these bodies spot welded?

A. Well, the body came to us in five pieces with a two piece over-lap and the welds were spotted about two and one-half to three inches.

Q. 14. How did the electrodes contact with the over-lapped beads?

A. There was a pointed die on the bottom which is stationary and the top die is flat, about one and one-half inches in diameter, and we worked the top die by hand-lever—on one machine we used the hand lever and on one the foot tread.

Q. 15. When these dies came together, what did they do?

A. Most generally weld.

Q. 16. Is this what you call spot welding?

A. Yes.

Q. 17. Do I understand these welding spots are spaced apart along the bead?

A. Yes, spaced along the bead; from two to three inches.

Q. 18. For whom were these automobile bodies made?

A. For whom were the made?

Q. 19. Yes—by the O. J. Beaudette Co. of Pontiac, Mich.?

A. Ford Motor Company.

Q. 20. And have you been making automobile bodies for the Ford Motor Co. ever since?

A. Yes—I have been, excepting sixteen days I worked over to the General Motor Co. last fall.

Q. 21. Are you quite positive that you did spot welding work on Ford Automobile bodies in October, 1912?

A. I am.

Q. 22. And were these the regular standard product for the Ford Motor Co.?

A. They were.

Cross-examination by MR. MCDOWELL:

(Having objected to the taking of testimony at this time, reserve right to cross-examine witness as to matters testified to in said examination until such further time as may be determined.)

Signature waived by consent of counsel.

FRANK E. MILLS.

FRANK E. MILLS, being duly sworn, deposes and says in answer to interrogatories propounded to him by MR. O. F. BARTHEL, as follows, to wit:

Direct Examination.

Question 1. What is your name, age, residence and occupation?

Answer. Frank E. Mills; age 38; residence 228 Orchard Lake Ave., Pontiac, Mich.; occupation Assistant Manager, O. J. Beaudette & Co., Pontiac, Michigan.

Q. 2. How long have you been engaged with said company?

A. Since 1901.

Q. 3. What product does said Company make?

A. Automobile bodies.

Q. 4. For what companies?

A. At the present time, only the Ford Motor Co.

Q. 5. How long have you been making bodies for the Ford Motor Co.?

A. Since 1907.

Q. 6. Have you missed any years since that time?

A. None.

Q. 7. What is your work in connection with the making of these bodies?

A. I have always figured and estimated the cost of the bodies.

Q. 8. And in connection with the estimating of costs, for bodies, are you furnished with any data from which to make these estimates?

A. Yes.

Q. 9. I hand you herewith a blue print and would ask you if you have ever seen this print or a copy thereof in connection with any of your estimating work?

A. Yes, this is the construction of body I remember well.

Q. 10. For what model car was this body, if you recollect?

A. 1913 Model.

Q. 11. How is it that you remember this body well?

A. I recollect a few weak points that developed after we started to get and after we got same out.

Q. 12. About when was this body submitted to you for estimating?

A. In the summer of 1912.

Q. 13. I notice this drawing is dated June 21st, 1912. Would you say that it was shortly after this time?

A. Shortly after this time, I should say it was.

Q. 14. Is there anything else which enables you to remember this particular type of body well?

A. Yes, that is the first body we ever did any spot welding on.

Q. 15. Does this drawing show that?

A. It shows it here and here and here—(witness points to beads on drawing or blue-print—marked "X" in pencil).

(Counsel for defendant requests that the blue print referred to by the witness be marked for purposes of identification "Blue Print Ford Touring Car—Spot Welded Body.")

Q. 15. You state that this body was for the 1913 model? Now, do you know when the season begins?

A. For the different models?

Q. 17. For the different models? Each year?

A. It is supposed to begin August first.

Q. 18. What year?

A. For the preceding year—that is when it is supposed to begin.

Q. 19. That would be August 1st, 1912?

A. August 1st, 1912, yes.

Q. 20. So that in the summer of 1912 you began to get ready for the 1913 model, is that correct?

A. Yes.

Q. 21. About when were the spot welders secured for this job?

A. Between July and November or December of 1912.

Q. 22. And about what time did you begin getting up material for these jobs?

A. About in August or September—probably.

Q. 23. I hand you herewith memorandum sheet dated August 31, 1912, and would ask you what this is?

A. This is a list of metal that we used on the 1913 touring car for the Ford Motor Company.

Q. 24. Does that show the particular parts of the job which were cut up and spot welded?

A. Yes.

Q. 25. Will you mark them with pencil?

(Witness does so, marking same with the letter 'X'.)

Q. 26. Is this one of the original lists of your company?

A. Yes.

(Counsel for defendant offers in evidence list referred to by witness and instructs Notary to mark same "Defendants Exhibit Metal List for 1913 Touring Car."

Q. 27. About when did you go into production on these spot welded bodies?

A. In October, 1912.

Q. 28. And did you see some of these bodies welded at that time?

A. I did.

Q. 29. How were they welded?

A. Spot welded.

Q. 30. At what points?

A. Along the bead from two to three inches—the full length of the bead.

Q. 31. By bead what do you mean?

A. That is the pressed-out part—half oval shape.

Q. 32. And do these parts overlap each other?

A. The beads overlap each other, welded on the piece.

Q. 33. And these bodies were regular standard production of the Ford Motor Company at that time, were they?

A. They were.

Q. 34. Have you any record which would show when this spot welding work was done?

A. Yes.

Q. 35. Will you produce it?

A. Yes—the Superintendent's book.

Q. 36. Is he here in the shop?

A. He is—yes.

Q. 37. Have you looked up to find the records of the Company in reference to this Ford body work?

A. Tried hard to look them up.

Q. 38. And did you succeed in finding the records?

A. No.

Q. 39. What became of them?

A. They were destroyed in the Spring of 1917.

Q. 40. How did it happen that they were destroyed?

A. They were placed in a vault at the east end of the factory where our office formerly was and during a heavy rain, or thaw, in the Spring of 1917 they were destroyed thru water getting into the vault—destroying all papers that were in there.

Cross-examination by MR. MCDOWELL:

(Having objected to the taking to the testimony at this time, reserve right to cross-examine as to matters testified to in said examination until such further time as may be determined.)

Signature waived by consent of counsel.

M. L. EVELY.

M. L. EVELY, being duly sworn, deposes and says in answer to interrogatories propounded to him by MR. O. F. BARTHEL, as follows, to wit:

Direct examination:

Question 1. What is your name, age, residence and occupation?

Answer. M. L. Evely; age 48; residence Pontiac, Mich.; occupation Superintendent, O. J. Beaudette & Co., Pontiac, Mich.

Q. 2. How long have you been connected with the O. J. Beaudette Co.?

A. Nine years.

Q. 3. And what do they manufacture?

A. Automobile bodies.

Q. 4. During the nine years that you have been connected with them, what automobile bodies have been manufactured by them, principally?

A. Ford's, principally.

Q. 5. And how were these bodies assembled so far as relates to the subject-matter in the suit?

A. Just what do you mean by that?

Q. 6. I mean in reference to the uniting of the parts of the sheet metal body?

A. You mean by spot welding, riveting, etc., like that? The way they are united is by spot welding and riveting.

Q. 7. Why do you rivet in places?

A. Riveting is in places where you do assembling; where you could not handle spot welding.

Q. 8. When did you first make bodies which involved spot welding?

A. According to my private records I started in October, the 26th of October, 1912.

Q. 9. You started to make what?

A. Bodies that were spot welded together.

Q. 10. Were they standard Ford automobile bodies?

A. Yes, they were.

Q. 11. Were they manufactured for the trade?

A. They were.

Q. 12. About how long prior to this time did you rig up for the manufacture of these bodies?

A. Oh, well, I could not say definitely but it took us probably about three months. It takes quite a long while to get our dies out.

Q. 13. From October 26, 1912, and prior to December 3, 1912, how many Ford automobile bodies did your plant turn out in regular production that included these spot welding features?

A. 3,345.

Q. 14. And these were made for the Ford Motor Company?

A. For the Ford Motor Company.

Q. 15. Where was this spot welding on these bodies?

A. On the corners of the rear seat.

Q. 16. How was this spot welding done?

A. Well, to unite the five pieces comprising this assembly into an assembly. I can name the pieces if you wish it—the way we term them.

Q. 17. Were the pieces overlapped?

A. They were.

Q. 18. And were they beaded along this overlapped portion?

A. They were.

Q. 19. And how were they spot welded on this overlapped beaded portion?

A. In the center of the bead.

Q. 20. How were these spot welds placed?

A. Distance apart—about two and one-half to three inches apart.

Q. 21. Will you explain just how the operator would make one of these welds?

A. First of all we take the seat quarter and the corner panel,

both of these have a bead on the edge; one is placed on top of the other one, and spot welded. The bead locates the two pieces in its proper place. Then we move that along on the spot welder from bottom to the top of the seat at intervals of two and one-half to three inches apart.

Q. 22. At these intervals of two and one-half to three inches apart, what takes place?

A. Welds.

Q. 23. How are these welds made?

A. By electricity.

Q. 24. Will you explain how this is done?

A. The contacts are made by two copper points and the work is placed between these two points, and when you trip the machine it throws the current on, the iron being of a nature that will weld. This is really all there is to a weld.

Q. 25. By iron I take it you refer to the sheet metal, do you not?

A. Yes.

Q. 26. I understand that your company records have been lost in a flood which you had some years ago. Is that right?

A. I believe it is, when we moved from the other office up here a lot of our records were lost, and I could not just say what they were, but I know we lost a lot—a great many of our records.

Cross-examination by MR. MCDOWELL:

(Having objected to the taking of testimony at this time, reserve right to cross-examine witness as to matters testified to in said examination until such further time as may be determined.)

Signature waived by consent of counsel.

Adjourned at 5.00 o'clock P.M., to the Office of the Ford Motor Co., Highland Park, Michigan.

Parties met at the Offices of the Ford Motor Company, Highland Park, Michigan, present as before, and the taking of testimony was resumed at 11.30 o'clock A.M., July 25, 1919.

Counsel for defendant gives notice that he will take the testimony of Hubert E. Hartman, Legal Department, Ford Motor Company, in addition to the witnesses before named.

Counsel for defendant offers in evidence copy of decision of Board of Examiners-in-Chief dated June 24, 1919, in Re. Appeal 2844, S. Z. de Ferranti versus Johann Harmatta for improvements in electric welding.

JOHN J. FINDLATER.

JOHN J. FINDLATER, being duly sworn, deposes and says in answer to interrogatories propounded to him by MR. O. F. BARTHEL, as follows, to wit:

Direct examination:

Question 1. What is your name, age, residence and occupation?

Answer. John J. Findlater; age 36; residence 101 Tuxedo Ave., Highland Park, Mich.; occupation Assistant Superintendent, Ford Motor Co., Detroit, Mich.

Q. 2. How long have you been employed by the Ford Motor Co.?

A. I have been at this plant since May, 1913. Before that in the Ford Motor Co. Pressed Steel plant in Buffalo that was acquired in June, 1911.

Q. 3. And prior to that time where were you employed?

A. In the same plant that was known as the John R. Keims Mills, Inc., Buffalo, N. Y., since 1903.

Q. 4. What were your duties at the John R. Keims Mills, Inc., Buffalo, N. Y.?

A. When I started there I was employed as a tool and die maker. Afterwards I had charge of the Press Dept. and of the Tool Room, as Tool Foreman. Later on I was General Foreman of the entire plant.

Q. 5. Prior to the John R. Keims Mills, Inc., of Buffalo, N. Y., being taken over by the Ford Motor Co., did you do any work for the Ford Motor Co.

A. Almost exclusively.

Q. 6. What class of work was that?

A. Transmission cases, rear axle housings, gasoline tanks, fenders, running board shields, steering columns; in fact practically all of the pressed steel parts or the sheet metal parts.

Q. 7. And was this plant known as the Pressed Steel Plant after it was taken over by the Ford Motor Co.?

A. Yes—by the letterheads and the stationery it was known as the Ford Motor Co., Pressed Steel Plant.

Q. 8. After this plant was taken over by the Ford Motor Co. in June, 1911—did you see any other work done there?

A. Yes—they made a steel body.

Q. 9. How was this body made?

A. It was made entirely of steel, no wood was used in it. In taking place of the wood, there were steel sections along the bridge members, channel irons with reinforced holes in them all the way along. I was connected with that in the way of making tools to stamp out these different parts.

Q. 10. How were some of these parts united?

A. They were spot welded together; some riveted; some soldered.

Q. 11. Who worked with you in connection with the building of this body?

A. The body was built under the supervision of Wm. H. Smith and Knudson—these two men had charge of it—that is, they spent their personal time on it considerably.

Q. 12. What kind of machines were used that did the spot welding on this body in question?

A. We had a Winfield Spot Welder.

Q. 13. About when was this spot welder put in the plant?

A. I could not recall the exact date when it was put in.

Q. 14. Did you do some work on this spot welder?

A. I did some work on it myself, personally, in connection with fastening the flange on to the tube on the steering column.

Q. 15. And that was done by means of spot welds?

A. Yes.

Q. 16. About when was this spot welding work done?

A. The welding I did was from eight months to a year before I came here.

Q. 17. And you came here?

A. I came here in May, 1913.

Q. 18. In May, 1913?

A. Yes.

Q. 19. Do you know for what season or model this all-steel body to which you have referred was built?

A. The 1912 body.

Q. 20. Do you know what became of the welder that was used in the making of this body?

A. It was shipped to this plant here.

Q. 21. Did you afterwards see that welder in this plant?

A. Yes.

Q. 22. And is that welder still in use here?

A. I believe it is. I might say here I am familiar with that welder. I can recognize and identify it because it is of a different type than the welders we use right now. It looks different than the other ones. I have used it since I have been here.

Q. 23. And you have used it for spot welding?

A. Yes.

Cross-examination by Mr. McDowell:

(Having objected for the reason that Mr. Stackpole, counsel in charge of case for the plaintiff, is not present, by reason of the fact that he is engaged elsewhere in taking depositions in same cause, reserve right to cross-examine for future time if the Court shall determine this evidence proper.)

Signature waived by consent of counsel.

HARRY P. PROSSER.

HARRY P. PROSSER, being duly sworn, deposes and says in answer to interrogatories propounded to him by Mr. O. F. BARTHEL, as follows, to wit:

Direct Examination:

Question 1. What is your name, age, residence and occupation?

Answer. Harry P. Prosser; age 37; residence Pontiac, Mich., R. F. D. No. 6; occupation General Branch Assembly Work, Ford Motor Company, Highland Park, Mich.

Q. 2. I take it you have charge of the assembling of the parts which go into the cars for the branches, is that it?

A. I look after trouble work and general branch assembly conditions.

Q. 3. How long have you been connected with the Ford Motor Co.?

A. Since March 5, 1907.

Q. 4. What were your duties in connection with your earlier services with the company?

A. Draftsman in the Drafting Room.

Q. 5. And after that?

A. Along about 1911, I think it was, I was placed on the body work. My duties were to see that the body companies were kept in touch with information relating to drafting pertaining to bodies, and also trimming.

Q. 6. And did you have occasion to see this work in process of construction?

A. Yes, it was my duty to visit all body companies.

Q. 7. In your visit to these various plants, what, if anything, did you see which might have bearing in connection with this case?

A. They had spot welders that were used for our back panels by which I mean they used these machines for spot welding beads together.

Q. 8. What places did you have occasion to visit?

A. O. J. Beaudette Body Co., Pontiac, Mich., Wilson Body Co., Detroit, Mich., Kelsey-Herbert Body Co., Detroit, Mich. (now known as the Kelsey Wheel Co.), and the Fisher Body Corporation Detroit, Mich.

Q. 9. Did all these concerns build bodies for the Ford Motor Co.?

A. Yes, sir.

Q. 10. On any of your visits to the Beaudette Body Co. of Pontiac, Mich., what, if anything, did you see that might have bearing on this case?

A. I noticed the operation of spot welding these panels, which was exceedingly interesting due to the fact that they had plans for this design of job; about the only way they could do them.

Q. 11. How was that work done?

A. The panels were laid together with overlapping bead held by two men who placed them in that condition in the machine, and then a man with his foot would bring down one lever at the contact point and immediately the top point would fall on top of the metal panels which would allow, I presume, the current to pass through the metal, fusing the beads together. That would be the contact point underneath the beads and the upper contact point of the machine brought down on top of the metal beads caused the current to flow through and fuse the metal altogether.

Q. 12. Were these beads fused together throughout their entire length, or at the points where the contacts came together?

A. Where the contacts would come together, I think we specified something like two and one-half to three inches apart where the contacts would come.

Q. 13. About when was it that you saw this work at the Beaudette Plant?

A. Our drawings were turned over to Beaudette in the summer of 1912, and it was my duty to follow the work from that time on. I first noticed the spot welding operation along in the fall, in October, I believe, more particularly because my attention was called to the fact that they were having difficulties with their work, and I was out in the factory considerably and noticed conditions and that is how I noted the spot welding work.

Q. 14. But you did go into the quantity production basis on these bodies?

A. Well, the production end I did not have so much to do with. The quantity turned out was not very great until along the latter part of the month of October.

Q. 15. Where was this idea of spot welding these panels together along the beading developed?

A. Why, along back in the early part of 1911, before I went out to the body works, Mr. Wills had a Mr. Kratz working on an all-metal body, similar in shape according to this drawing, and the only way that they could work this out was by using the method of welding the panels together, because the design was carried out similar to this design here. (Witness referring to blue-print already offered for identification.)

Q. 16. Was there anything furnished the O. J. Beaudette Body Co. from which to make the bodies of which you have been testifying?

A. They had a print similar to this one here. (Witness referring to blue-print already offered for identification.) I think Mr. Wills and the O. J. Beaudette Body Co. were in consultation previous to receiving the print.

Q. 17. I hand you herewith print to which you have just referred and would ask you if that shows the type of body to which you have referred?

A. Yes, sir. It shows the shape of the beadings; one overlapping the other.

Q. 18. Is there anything particular about this body which enables you to fix the year as 1912?

A. Our dates are on there at time drawing was submitted.

Q. 19. What date do you find thereon?

A. Shows date on here of June 21, 1912.

Q. 20. And do you find any reference thereon in reference to spot welding?

A. There is a note on here which says "to be spot welded not over

two inches in length on moulding." That word "moulding" is sometimes used in place of beading.

Q. 21. And has this inscription in reference to spot welding been on this drawing ever since the date which it bears, June 21, 1912?

A. I think it has, yes, sir.

Q. 22. Did you have anything to do with the making or development of this drawing or type of body?

A. Yes, sir, it was my duty from time to time to see that drawings were brought up to date on changes which were considered necessary, and each time the date was put on and what the change happened to be.

Q. 23. But no change has been made affecting the spot welding on the moulding or bead, is that right?

A. No, sir, no change has been made.

Q. 24. Do you know about when the Kelsey-Herbert Co. started production on that same type of body?

A. It was about the time Beaudette started their production. I think it was along in November.

Q. 25. And you saw spot welding bodies also made at this plant?

A. Yes, sir.

Q. 26. All of these bodies were used in the regular production of the Ford Motor Co.?

A. Yes, sir.

Q. 27. Where did you get this drawing or blue-print about which you have been testifying?

A. This print was made from drawing which we have in drafting room at the present time. An ink tracing.

Q. 28. And that drawing is being kept for reference in the drafting room?

A. Yes, sir.

Q. 29. So that it would not be convenient to have that drawing go out of your possession?

A. I hardly believe they would let me take it out of there. The print is an exact duplicate of the drawing.

(Counsel for defendant offers in evidence the blue-print or drawing referred to by witness marked "Defendant's Exhibit Touring Car Body T 5403-1913" the blue-print being substituted for the original drawing with the understanding that the original will be produced at any time for purposes of inspection and comparison.)

Q. 30. I notice that this drawing bears a 1913 date within the circle containing the letter T-5403—to what does that refer?

A. That refers to the 1913 design. Our fiscal year production started in August and this body was designed and brought forward so that they could produce it for our 1913 work.

Q. 31. What time in August does your fiscal year start?

A. I don't know at just what date but it's along about July 31st or the first of August.

Q. 32. And this is of the year previous so that the fiscal year would start in August, 1912, for the 1913 season, is that correct?

A. Yes,—that's the idea.

Q. 33. Those bodies made by the O. J. Beaudette Co. and the Kelsey-Herbert Co. were regular standard output of the Ford Motor Co., were they not?

A. Yes—regular output.

Q. 34. And they were made for your company as regular production and under your supervision?

A. Yes, sir.

Q. 35. And the quantity production commenced in October, 1912?

A. Along about October, 1912—yes, sir.

Q. 36. And these concerns rigged up for their manufacture some months prior to October, 1912?

A. Yes, they commenced to get ready, as soon as their contracts were given.

Cross-examination by MR. MCDOWELL:

(Having objected for the reason that Mr. Stackpole, counsel in charge of case for the plaintiff, is not present, by reason of the fact that he is engaged elsewhere in taking depositions in same cause, reserve right to cross-examine for future time if the Court shall determine this evidence proper.)

Signature waived by consent of counsel.

Adjourned at 12.30 o'clock P. M.

Resumed 1.30 o'clock P.M.

HUBERT E. HARTMAN.

HUBERT E. HARTMAN, being duly sworn, deposes and says in answer to interrogatories propounded to him by MR. O. F. BARTHEL, as follows, to wit:

Direct examination:

Question 1. What is your name, age, residence and occupation?

Answer. Hubert E. Hartman; age 34; residence 345 Elmhurst Ave., Highland Park, Mich.; occupation Chief Attorney for the Ford Motor Co., Highland Park, Mich.

Q. 2. You have charge of the Legal Department of the Ford Motor Co.?

A. Yes, sir.

Q. 3. I hand you herewith revised list of the contributors of the Welding Patents Investigating Committee and notice the name of the Ford Motor Company thereon as one of the contributors, and would ask you what you have to say to this?

A. The Ford Motor Co. contributed in a limited sort of a way to this Investigating Committee Fund for the purpose of investigating the merits of a patent, determining what our action should be with reference to recognition of a patent. We contributed twice, I think, under a special arrangement whereby we reserve at all times a separate and independent action and without prejudice to any action we might wish to take independent of the Committee. Contributions were also made upon the understanding that we did not thereby become bound by any obligations to assist in the defense of any action brought against any member of the Committee or contributing party to the fund, reserving at all times the right to decide for ourselves if action should be brought against us whether or not we would avail ourselves of the evidence gathered by the Committee or ask them for assistance in defending the case. When suit was brought against us, after a conference with Mr. Henry Ford, Mr. Alfred Lucking of counsel for this company, it was decided that in accordance with the continued policy of this company, we would defend the case ourselves independent of the Welding Patents Committee. We therefore arranged with our attorneys for our own defense and have so conducted it since.

Q. 3. Have you paid all the bills in connection with the conduct of the defense?

A. We have paid all bills we have any knowledge of. Many thousands of dollars have been paid by us during the progress of the suit to our own attorneys and for expenses and the taking of their testimony.

Q. 4. The original contributions to the Welding Patents Investigating Committee, I take it then, were merely for the purpose of investigating the prior art?

A. Yes, that would be the way I would put it. I might also say that Mr. Ford instructed us personally never to become bound by an agreement in defense of this suit with any other parties who might be interested in it. And it has also been his policy to fight his own patent battles.

Q. 5. I take it, then, that you reserved the right of independent action?

A. Yes.

Q. 6. Do you know whether the moneys contributed for investigation purposes by your company were kept in a separate account?

A. We asked that they be so kept and received a letter from Mr. Milligan (I think it was), Chairman of the Committee stating he was keeping our contributions separate from that of the other contributors, in accordance with our request.

Q. 7. Am I to understand that your company has paid all of the expenses so far incurred in connection with the suit in which you are now testifying?

A. I can say we paid all expenses which we have been called upon to pay; which were represented by attorneys' fees of our attorneys, Barthel-Flanders and Barthel, together with the other counsel he has had assist him and all expenses of preparation of the defense.

Q. 8. No moneys have been received by you or other contributions from the contributors included in the revised list of contributors dated July 17, 1917?

A. No.

Q. 9. Did your company agree to contribute to the defense of any member of the Committee that might be sued under the Harmatta Patent?

A. No, sir.

Q. 10. As the head of the Legal Department, the defense of this suit has been under your control, exclusively.

A. Yes, sir.

Q. 11. Was there ever any permission given to use your name in connection with the list of contributors?

A. No, sir.

(Counsel for defendant offers in evidence revised list of contributors to Welding Patents Investigating Committee, and instructs Notary to mark same "Defendant's Exhibit Bulletin No. 21—July 17, 1917.")

Q. 12. Has the conduct of this case been influenced in any way by any action which the Welding Patents Committee may have taken?

A. No.

Cross-examination by MR. MCDOWELL:

(Having objected for the reason that Mr. Stackpole, counsel in charge of case for the plaintiff, is not present, by reason of the fact that he is engaged elsewhere in taking depositions in same cause, reserve right to cross-examine for future time if the Court shall determine this evidence proper.)

Signature waived by consent of counsel.

A. M. WIBEL.

A. M. WIBEL, being duly sworn, deposes and says, in answer to interrogatories propounded to him by MR. O. F. BARTHEL, as follows, to wit:

Question 1. What is your name, age, residence and occupation?
Answer. A. M. Wibel; age 33; residence 142 Collingwood Ave.,

Detroit, Mich.; occupation Mechanical Engineer, Ford Motor Co Highland Park, Mich.

Q. 2. With what company are you connected as Mechanical Engineer?

A. Ford Motor Company, Highland Park, Mich.

Q. 3. How long have you been connected with them?

A. Seven years—since May 3, 1912.

Q. 4. What are your duties with the Ford Motor Co. in your capacity as mechanical engineer?

A. Specification of all machinery equipment; purchasing same; lay-out of machine operations and other relating work.

Q. 5. In the purchase of machine equipment, do you have occasion to purchase spot welding machinery?

A. Yes, sir.

Q. 6. When did you on behalf of your company make the first purchase of this class of spot welding machinery for the Detroit plant?

A. According to my records this purchase was made the 20th of August, 1912. Received in our plant 19th of September, 1912.

Q. 7. For what kind of a machine was this purchase?

A. This particular purchase was made for a Winfield Spot Welding machine—S-6-M-Electric Spot Welder—Winfield Serial No. 2157.

Q. 8. And about how soon after this machinery was received in September, 1912, was it put into operation?

A. In ordinary practice, after machinery is received in this plant it is put in operation about five days. This time may vary according to the type of machinery, and the amount of work necessary to set it up and put it in operation.

Q. 9. But ordinarily you are behind in machinery equipment so that its installation is urgent?

A. With very few exceptions, equipment is so urgently needed immediately upon its receipt in the shop it is put in operation at the quickest possible time.

Q. 10. Prior to the purchase of this machinery which I understand was the first spot welding purchased for use at the Detroit plant, had your company purchased any other machines?

A. Of this particular kind?

Q. 11. Any other spot welding machines?

A. Not to my knowledge. I believe this spot welder is the first we have ever purchased for use in this particular plant, through the engineering department. Our records show this to be the first machine.

Q. 12. When the John R. Keim Mills, Buffalo, N. Y., was taken over by your company, were there any spot welding machines purchased from them?

A. There was one spot welding machine in the possession of the John R. Keim Mills, but the records would show whether that was in our possession at that particular time or whether it had been pur-

chased through them and used by us. I refer to Winfield Spot Welder—their serial number 318. Our records show that this particular welder was purchased in Buffalo to be used for our body pressed steel work, same as was being done by the John R. Keim Mills.

Q. 13. Can you give the year?

A. This was along in July or August, 1912, to my knowledge and from the records the machinery had evidently been used some time before that. The records show this particular machine was purchased in 1911, through the John R. Keim Mills of Buffalo, N. Y.

Cross-examination by MR. MCDOWELL:

(Having objected for the reason that Mr. Stackpole, counsel in charge of case for the plaintiff, is not present, by reason of the fact that he is engaged elsewhere in taking depositions in same cause reserve right to cross-examine for future time if the Court shall determine this evidence proper.)

Signature waived by consent of counsel.

Adjourned from Friday, July 25, to Monday, July 28, 1919, at 3.00 P.M. o'clock.

WILLIAM H. SMITH.

WILLIAM H. SMITH, being duly sworn, deposes and says, in answer to interrogatories propounded to him by MR. O. F. BARTHEL, as follows, to wit:

Question 1. What is your name, age, residence and occupation?

Answer. William H. Smith; age 48; residence Detroit, Mich.; occupation Engineer, Ford Motor Co., Detroit, Mich.

Q. 2. How long have you been connected with the Ford Motor Co.?

A. Directly since 1912—associated with them in their work since 1905.

Q. 3. What do you mean by directly associated with the Ford Motor Co. since 1912?

A. I became a part of the organization of the Ford Motor Co. in 1912 when they bought the plant I was with at that time.

Q. 4. What plant was it that they bought?

A. John R. Keim Mills, Inc., Buffalo, N. Y.

Q. 5. How long were you associated with them?

A. I was one of the organizers of the company, which was in the year 1900.

Q. 6. What was your official capacity with that company?

A. General Manager.

Q. 7. And that company was afterwards taken over by the Ford Motor Company?

A. It was, yes.

Q. 8. When was this?

A. Fifty per cent of the stock was taken over pro-rata by the stockholders of the Ford Motor Co. in 1911 and one hundred per cent of the stock of the company was taken over by the Ford Motor Company in the early part of 1912.

Q. 9. When this plant was taken over by the Ford Motor Co., was it continued to be called the John R. Keim Mills, Buffalo, N. Y.?

A. No, it was called the Ford Motor Co. Pressed Steel Plant.

Q. 10. It was known as the Pressed Steel Plant, is that right?

A. Yes.

Q. 11. What class of work was done at this plant?

A. Making of sheet metal, sheet steel frames and parts for automobile construction.

Q. 12. Did you do any work there which might have any bearing on the matter here in controversy?

A. What is the matter in controversy?

Q. 13. Spot welding?

A. We built and developed the first steel body that was made for the Ford car at that plant in 1911, that was spot welded.

Q. 14. In what way was this body spot welded?

A. Where the sheet parts joined each other—where they attached to the frames composing the body.

Q. 15. With what kind of a machine was this spot welding work done?

A. With a machine we purchased from the Winfield Co. at Warren, Ohio. At the two contact points, the current was turned on when the lever was brought down by a pressing action.

Q. 16. And how were the metal sheets placed in the machine for welding?

A. The two sheets were held in the machine by hand; this was a developing job at that time and not a production job.

Q. 17. Was the Winfield machine to which you refer one of those put out by the Winfield Electric Welding Co. of Warren, Ohio?

A. Yes, it was from the Winfield Electric Welding Co. of Warren, Ohio.

Q. 18. And about when was this purchased?

A. The date on the order was about March, 1911. The order was placed along about February and we got our machine in March or April.

Q. 19. And was it put to use as soon as received?

A. Yes—we were waiting for it.

Q. 20. What was it that gave you the idea of spot welding these bodies, if anything?

A. The idea of spot welding bodies was original with us. We

had made bicycle hardware and were acquainted with the welding process. When we started to design bodies we called in some builders of welding machines and told them what we wanted. Winfield visited the plant on our request for him there and he told us he was making a machine that was for spot welding and could be assigned to our purpose, with some little alterations.

Q. 21. I take it you refer to Mr. Winfield of the Winfield Electric Welding Company of Warren, Ohio?

A. Yes.

Q. 22. How were the welding spots located on this body?

A. They would be close to the edge where the two metals came together probably an eighth of an inch from the edge and then the spots go along at intervals of one and one-half to two inches according to what strength was required.

Q. 23. That is along the line where the adjacent edges of the sheet metal body overlap?

A. Yes. At that time, understand, the bodies were not made in a single piece. There were two seats to a body proper—the seats were detachable.

Q. 24. And the spot welding work was done in connection with this type of body?

A. It was.

Q. 25. Do you remember for what year or model this body was made?

A. This work was done on the original design of job that existed in 1910 and 1911 and that body was finished and sent here and the work was held pending new design for 1912, and that is why we did not continue with it.

Q. 26. When the new design of 1912 came out, did you take up with any companies the matter of making these bodies?

A. Making the new design?

Q. 27. Yes.

A. The new design I took up with the Fisher and Beaudette Companies personally and explained our method of construction.

Q. 28. Was the spot welding used in connection with these bodies?

A. It was, yes.

Q. 29. And so far as you know, they purchased welding machines for this work?

A. Yes, I think the same kind of a welding machine was purchased—from the same design we used—the Winfield—in the case of Beaudette.

Q. 30. When did you leave the Buffalo plant and come to the Highland Park plant of the Ford Motor Co.?

A. In July, 1912.

Q. 31. And was all this work done prior to your coming to Detroit?

A. The developing of the body and making of the body and welding in Buffalo was done prior to my coming here.

Q. 32. So that you are quite positive that the spot welding work

had been carried out in Buffalo prior to your coming to Detroit in July, 1912?

A. Very positive—I directed it; carried it out.

Q. 33. Do you know John J. Findlater?

A. I do.

Q. 34. Where did you become acquainted with him?

A. He was one of the foremen in the John R. Keim Mills at Buffalo, N. Y.

Q. 35. Did he have anything to do with this work so far as these spot welding machines were concerned?

A. I don't recall now that he had anything to do other than what a tool maker would have to do in building parts. He was acquainted with the machine being there, but I don't believe he had anything to do with the operating of it.

Q. 36. He had something to do with the building of the tools for the machine?

A. Yes, building tools and the tools used in making body parts, but not operating of the machine—that was under the experimental division.

Q. 37. By tools I take it you include dies for the body as well, do you not?

A. There were no dies made for this body. The pieces were cut out and fitted in. What I mean by tools are fixtures and points that would go on the welding machine.

Q. 38. He had to do with the keeping of that machine in running order?

A. He was one of the men that responsibility would come under.

Cross-examination by MR. MCDOWELL:

(Having objected to the taking of testimony at this time, reserve the right to cross-examine witness as to matters testified to in said examination until such further time as may be determined.)

Signature waived by consent of counsel.

DISTRICT COURT OF THE UNITED STATES

EASTERN DIVISION OF MICHIGAN

SOUTHERN DIVISION

THOMSON SPOT WELDER COMPANY

vs.

FORD MOTOR COMPANY

In Equity.

DEPOSITION TAKEN ON BEHALF OF THE DEFENDANT UNDER THE EQUITY RULES OF THE SUPREME COURT, UNDER THE REVISED STATUTES, BEFORE W. S. HELSLEY, ACTING AS SPECIAL EXAMINER BY CONSENT OF COUNSEL.

Warren, Ohio, October 25, 1919.

J. L. Stackpole, Esq., counsel for plaintiff; Melville Church, Esq., and A. S. Pattison, Esq., counsel for defendant.

Certificate of officer and signature of witnesses waived.

MR. GEORGE B. SAWYER, being called as a witness on behalf of the defendant and being first duly sworn, testifies as follows to questions by Mr. A. S. Pattison:

Question. Please state your name.
Answer. George B. Sawyer.
Q. Where do you live?
A. Warren, Ohio.
Q. What is your occupation?
A. Purchasing agent.
Q. For what Company?
A. Peerless Electric Company.
Q. How long have you been connected with the Peerless Electric Company?
A. Since the organization in 1902. Sixteen years, practically.
Q. What was your occupation prior to your employment by the Peerless Electric Company?
A. Preceding was with the Warren Electric and Specialty Company.
Q. How long had you been with that Company?
A. Some three or four years.

Q. What were your duties with the Warren Electric and Specialty Company?

A. I was purchasing agent there.

Q. Were you familiar with their catalogues and advertising matter?

A. I saw their catalogues and advertising matter and more than likely placed the order for the work.

Q. Do you know whether the Warren Electric and Specialty Company preserved in any way any of their catalogues and advertising matter?

A. They did.

Q. In what way?

A. At one time in scrap book form.

Q. I show you a book and ask you if you know what that book is?

A. I recognize the book as the old scrap book of the Warren Electric and Specialty Company.

Q. Do you know where that book has been; I mean what Companies have had this scrap book?

A. On the organization of the Peerless Electric Company it passed to them, as I understand it.

Q. From what Company?

A. The Warren Electric and Specialty Company.

Q. Has this book been in the possession of the Peerless Electric Company from the time it was turned over to them by the Warren Electric and Specialty Company?

A. For anything I know it has been here ever since, continuous.

Q. State whether, if you know, the Warren Electric and Specialty Company issued catalogues and bulletins of their desk fans?

A. They did. That was their custom, their practice.

Q. I call your attention to bulletins numbers 1, 2, 3 and 4, which are pasted in this scrap book, and ask you whether you recognize those bulletins?

A. I do.

Q. When were they published?

A. 1901. I think all of them.

Q. Do you mean for the season of 1901?

A. Yes, sir.

Q. Please explain, if you know, what was the object in issuing these bulletins?

A. I think it was to supplement the catalogue issue. The bulletins were sent out to the agents of the Warren Electric and Specialty Company and circulated as advertising matter.

Q. Am I correct in understanding that this scrap book was the property of the Warren Electric and Specialty Company and passed from them to the Peerless Electric Company when the latter Company purchased the Warren Electric and Specialty Company?

A. Your question is not quite right. The Peerless Electric Com-

pany did not purchase the Warren Electric and Specialty Company. When they organized the Warren Electric and Specialty Company was sold absolutely. The Peerless Electric Company was organized as a distinct and new company. They took over some things, however.

Q. State, if you know, whether the Peerless Electric Company took over the fan business of the Warren Electric and Specialty Company?

A. They did.

Q. And in taking over this they took at the same time this scrap book?

A. That was a part of the inheritance.

(The scrap book testified about by the witness is offered in evidence on behalf of Defendants and it is marked "Warren Electric and Specialty Company and Peerless Electric Company catalogue and bulletin scrap book number A-A-A-A.")

Cross-examination by MR. STACKPOLE:

X-Q. Mr. Sawyer, I find in this scrap book a number of references to the Colonial Fan and Motor Co. What relation, if any, had that Company to the Peerless Company?

A. Well, the Colonial Fan and Motor Company was simply a selling agency of the Peerless Electric Company. They manufactured nothing themselves.

X-Q. They sold the Peerless Fan?

A. Sold the Colonial Fan, made by the Peerless Electric Company.

X-Q. Did they sell any fans not made by the Peerless Electric Company?

A. Not to my knowledge.

X-Q. That is all.

MR. F. P. MCBERTY, being called as a witness on behalf of Defendants and being first duly sworn, testifies as follows to questions by Mr. A. S. Pattison:

Question. Are you the F. P. McBerty who has previously testified in this case?

Answer. I am.

Q. You testified in this case before Judge Killits that you were connected with the fan department of the Warren Electric and Specialty Company and also their successors, the Peerless Electric Company?

A. I did.

Q. Please explain the construction of the desk fan blade or blades, as the case may be, that were manufactured and sold by

the Warren Electric and Specialty Company during the season of 1901?

(This testimony is objected to as not in response to the last testimony taken by the plaintiff.)

A. They had a desk fan made up with a steel spider which constitutes the center hub or support arms for carrying the blades, to which the blades were in some instances riveted, and the same general construction consisting of a steel spider in which the blades were spot-welded and also they had fan blades with a brass center which constituted the hub and a support arm for the fan blades, these blades riveted to the brass centers.

Q. How many rivets did the fan blades have which contained the brass center?

A. They had three rivets to the blade.

Q. How many rivets to the blade did the fan blades have which contained the steel center to which you have referred?

A. Two rivets to the blade.

Q. State what difference, if any, there was in the construction of the steel center with the two rivets for each blade and the steel center which you say was spot welded to the blades?

A. Steel center that was riveted to the blades were provided with holes punched to receive the rivets, the blades also had corresponding holes punched to receive the rivets, and the spot welded had no holes punched in the extended arms and the blades had no holes punched.

Q. Am I correct in understanding that the Warren Electric and Specialty Company manufactured and put on the market in the season of 1901 three types of desk fan blades, one with a brass center riveted to the blades, one with a steel center riveted to the blades and one with the steel center spot welded to the blades?

A. You are correct in that statement.

Q. Do you know whether the Warren Electric and Specialty Company issued catalogues and bulletins illustrating their desk fan products?

A. Yes, they did.

Q. Do you know what, if anything, was done to preserve any of these advertising catalogues or bulletins?

A. They had what was commonly called a scrap book into which they pasted copies of the various bulletins, catalogues and leaflets, as well as pages out of mechanical and electrical journals which carried illustrations of these products.

Q. Would you be able to recognize that scrap book?

A. I would.

Q. I call your attention to the book before you and ask you what that is?

A. That is the scrap book that was used for this purpose of preserving the advertising matter.

Q. State, if you know, what was done with this book when the Warren Electric and Specialty Company sold out its fan business?

A. This book passed into possession of the Peerless Electric Company, who purchased the fan motor interests of the Warren Electric and Specialty Company.

Q. The Peerless Company referred to by you, is that the Company which is occupying this office where we are now taking the deposition?

A. Same Company.

Q. I call your attention to bulletin number one, which is pasted in this scrap book, Defendant's Exhibit A-A-A-A, and ask you whether that illustrates either of the three types of fan blades which you say were manufactured and sold by the Warren Electric and Specialty Company in the year 1901?

A. That bulletin number one, season of 1901, illustrates the high grade desk fan equipped with the brass center blade with the three rivets mentioned.

Q. I ask you the same question in respect to bulletin number two?

A. Bulletin number two illustrates desk fan with the steel centers with the two rivet blade.

Q. I ask you the same question in respect to bulletin number three?

A. Bulletin number three illustrates the desk fan with brass center and three rivet blade.

Q. I repeat the question in respect to bulletin number four?

A. Bulletin number four illustrates Peerless fan with the steel center and spot welded blades or blades spot welded to the center.

Q. What season were these bulletins issued?

A. Those are in the season of 1901.

Q. What was the object, if you know, of sending out these bulletins?

A. Practice of sending out bulletins was adopted as it made it much easier to mail the circular covering a particular type of desk fan without sending a complete catalogue and also calling attention to the season's type.

Q. You have previously testified in this case that the steel center fan with two rivets to the blade was first manufactured and put on the market by the Warren Electric and Specialty Company for the season of 1901. What type of fan was this blade used on?

A. This blade was originally developed to take care of the demand for a comparatively cheap fan. The intention was to eliminate the expensive material used in the high grade fans.

Q. Which bulletin, if either of the four, to which I have called your attention shows the cheap type fan?

A. It is bulletin number four, illustrates the cheap fan.

Q. I notice and you have stated that bulletin number two has the steel center and the two rivets and this bulletin shows that type of blade attached to the "A-6" type of fan. What explanation, if any, have you to make in respect to this illustration?

A. This A-6 fan which is known as one of the high grade fans is apparently equipped with a fan blade having a steel center and possibly steel blades, brass plated, giving it the same appearance as a brass fan as far as the finish is concerned.

Q. How can the blade, the steel center blade as you say primarily developed for the cheap fan, be applied to the more expensive fan type "A-6" as shown in bulletin two?

A. I can best answer that question by saying that our fan shafts were all of a standard dimension, three-eighths of an inch in diameter, and any fan blade will fit any fan. This was standard practice with us all the time I was with the firm and still is.

Q. By that do you mean that the three types of blades manufactured for the season of 1901 were interchangeable in respect to the several fan motors that were manufactured with the different types of fans?

A. They were.

Q. Please state how many kinds, if more than one, of desk fan centers were manufactured and put on the market by the Warren Electric and Specialty Company for the season 1900?

A. Well, there was the brass strip center and the cast brass.

Q. Please examine the Warren Electric and Specialty Company's 1900 catalogue, which is pasted in the scrap book, Defendant's Exhibit A-A-A-A, and point out if you can the strip type of center that you refer to?

A. Well, this design is fully illustrated here on page eleven of the 1900 catalogue.

Q. How many rivets did this center have per blade?

A. There are two rivets per blade and four rivets in the center holding the strips to the hub.

Q. Of what material were the strips of this center made?

A. Made of brass.

Q. Does this catalogue show any other type of center than the strip one to which you have referred?

A. No, there is no other type of the center illustrated in this catalogue excepting the strip center.

Q. Was this strip center placed on the market by the Warren Electric and Specialty Company at a succeeding season after the year 1900?

A. It was not.

Q. Why?

A. The design proved too weak and ineffectual, causing a lot of trouble and expense. We were compelled to replace defective blades.

Q. By this do you mean that the strip brass center was abandoned after its use in the season of 1900?

A. Yes, it was entirely abandoned after the season of 1900 on account of this weakness.

Q. Have you examined the Plaintiff's Exhibit 51 now on file in the court at Detroit which is stated by the witness for the plaintiff to be a Warren Electric and Specialty Company's G-1 desk fan?

A. I have.

Q. When and where did you examine this?

A. I examined this fan in the clerk's office of the court in which this case is pending at Detroit, Michigan, on Thursday, October 23, 1919.

Q. Are you able to say whether this Plaintiff's Exhibit 51 does or does not contain a G-1 type of fan blade made by the Warren Electric and Specialty Company?

A. It is impossible for me to positively identify that fan blade as having been made by the Warren Electric and Specialty Company?

Q. Why?

A. There were other makes of fans being placed on the open market at that same time that had blades and centers of the same shape and design, same diameter, and would fit the same shaft.

Q. Please describe, if you noted, the general condition of the fan and its blade?

A. The motor itself together with its accompanying guard are in an excellent state of preservation; motor is clean; bearings are tight and the commutator is smooth, and apparently not been worn much. The fan blades are in bad mechanical condition, blades having been apparently bent repeatedly and the center itself is out of true, indicating hard usage and possible extended service.

Q. What, if anything, have you to say in view of these facts as to whether that motor and fan blade are the original motor and fan blade as sent out by the manufacturer?

A. From my knowledge of desk fans and motors I would say that that fan blade did not belong to that motor, or in other words, it was not the original blade sent out with the motor in question.

Q. Did you note the rivets on the fan blade of Plaintiff's Exhibit 51?

A. I did.

Q. What, if anything, did you notice about these?

A. These rivets have all indications of being machine riveted; that is, they have been riveted by a mechanically operated riveting machine.

Q. Did the Warren Electric and Specialty Company use a riveting machine of any kind that would produce the results shown on the fan blade, Plaintiff's Exhibit 51, during the year 1901?

A. No, they did not have any riveting machine at all, riveting all their fan blades by the aid of a rivet set and a hammer.

Q. Does the condition of the rivets on the fan blade of Plaintiff's Exhibit 51 enable you to say whether it could possibly be the Warren Electric and Specialty Company's 1901 blade?

A. That is impossible for me to say definitely. If the rivets are machine driven it could not have been made by the Warren Electric and Specialty Company.

Q. Are you familiar with the appearance of hand and machine headed rivets?

A. Yes.

Q. What is your opinion as to whether the rivets in the blade of Plaintiff's Exhibit 51 being hand headed or machine headed?

A. My opinion would be that they were headed up with aid of a machine riveter.

Q. While you were in Detroit on the 23rd did you examine the Plaintiff's Exhibits No. 40 and No. 41, which were offered in evidence as a fan motor and fan blade manufactured by the Warren Electric and Specialty Company?

A. I did.

Q. What, if anything, did you notice during this examination of these exhibits?

A. The thing that struck me most forcibly was that the fan blade did not belong on that fan motor.

Q. What enables you to say that?

A. The fan was a nickle plated blade, while the general finish of the fan motor is polished brass. A standard practice was to make all of the metal parts correspond in finish, being entirely polished fan known as the brass finish fan or all nickle plated, if it is known as the nickle plated fan.

Q. The 1901 Warren Electric and Specialty Company's catalogue, page 17, refers to "G" type of fan as "rigid Iron Clad Fans;" please explain, if you know, what this description of that fan means?

A. The intention of that description was to indicate that all of the parts of the fans that could be possibly made of iron were manufactured of that material such as the fan blades, fan centers, hubs and guards.

Q. In connection with the testimony of Robert W. Clark, the witness produced in rebuttal by the Plaintiff, there was offered in evidence as "Plaintiff's Exhibit 18, specimen of spot welding prepared by Clark," a number of spot welded specimens showing the spot welding of blades or bars of steel of various thicknesses. I have asked you to prepare a specimen of spot welding showing the parts of metals. If you have done so, will you please produce the same and explain it?

A. The samples that I have here are samples that I spot welded on one of my commercial welding machines of a similar type and consisting of two pieces of thin steel spot welded together; to one

piece of this thin steel is spot welded a piece of commercial tin-plate; and to this piece of commercial tin-plate is spot welded another piece of tin-plate of the same gauge and cut from the same sheet. To this second piece of tin-plate is spot welded a piece of black steel wire, and to this piece of steel wire is electrically welded a second piece of wire at right angles to the first piece.

Q. State what kind of electrodes you used?

A. This entire demonstration was done with the aid of two copper electrodes that are used in one of our standard spot welding machines.

Q. Please explain more fully the characteristics of what you have referred to as tinplate?

A. The tinplate, commonly known as commercial tinplate, consists of thin steel plate which is pickled to remove all impurities and scale and then dipped into a bath of melted tin which puts a fine deposit of tin over the entire surface of the plate on both sides.

(Defendants counsel offers in evidence the specimen produced by the witness and the same is marked "Defendant's Exhibit McBerty specimen exhibiting welding of different metals by use of copper electrodes.")

Q. Please produce if you can the copper electrodes of which the specimen just offered was welded?

A. I have here two copper electrodes that were used in this welding machine to produce the previous specimen or sample of spot welding.

(Defendant's counsel offers in evidence the electrodes just produced by the witness and the same are marked "Defendant's Exhibit McBerty copper electrodes used for spot welding different metals.")

Q. I now show you another specimen of spot welding work and ask you to tell us what it is and how it was made?

A. This second sample demonstration was produced from identically the same grade of material of the previous sample spot welded with the copper electrodes and consists of a thin piece of commercial steel sheet welded to another piece. Second piece of steel sheet is welded to a piece of commercial tinplate. This piece of commercial tinplate is spot welded to a second piece of tinplate of the same grade of material, and to this second piece is spot welded two pieces of black steel wire and to these two pieces of black steel wire is spot welded a third piece of black steel wire at right angles.

Q. What kind of electrodes was used in welding these specimens you have just described?

A. This specimen was welded in every particular with the aid of two steel electrodes made out of commercial cold roll steel bar, the points of same being approximately the same shape as our copper electrodes and being held in the same machine that was used in spot welding with the copper electrodes.

(Defendant's counsel offers in evidence specimen referred to in the last question and the same is marked "Defendant's Exhibit McBerty specimen exhibiting welding of different metals by use of steel electrodes.")

Q. Please produce, if you have them, the steel electrodes referred to in your preceding answer with which you welded your second specimen?

A. I have here the two steel electrodes which were used in our standard spot welding machine for producing the second specimen of sheet metal spot welding.

(Defendant's counsel offers in evidence the electrodes produced and the same are marked "Defendant's Exhibit McBerty steel electrodes used for spot welding different metals.")

Cross-examination by MR. STACKPOLE:

X-Q. Did you ever in 1901 or thereabouts weld steel fan blades to the arms of brass centers?

A. No, never did.

X-Q. What is the diameter of the copper electrodes used by you in making Defendant's Exhibit McBerty exhibit welding of different metals by use of copper electrodes? What was the diameter of the point of the electrodes?

A. The diameter of the electrode, the copper electrode itself, was seven-eighths of an inch, and the point of contact with the metal was approximately an eighth of an inch.

X-Q. How high was the bell from the end of the electrode, the part where it reaches its full width?

A. That is difficult to say without measuring, but approximately five-sixteenths of an inch from the end of the point to the upper edge of the bell.

X-Q. And what are the corresponding dimensions in the steel electrodes used by you in welding the other specimens?

A. Approximately the same. The intention was to make them the same dimensions and general shape.

X-Q. Do you equip any of your spot welding machines with steel electrodes like those in evidence for commercial use?

A. We do not.

X-Q. You made these specimens and used these electrodes at the request of counsel for the Defendant?

A. I did.

X-Q. In the case of the brass strip centers used by the Warren Company in 1900 were the strips fastened to the face of the hub?

A. They were.

X-Q. So that no part of the hub projected between the strips?

A. That question is rather indefinite. That is, between strips of the lateral surfaces?

X-Q. Yes.

A. There was no part of the hubs between the strips.

X-Q. On page fourteen of the Peerless catalogue of 1900 at the bottom the hub is shown as projecting between the strips or arms, is it not?

A. No, it does not show it extending between the strips. It extends up the side of the strips.

X-Q. Extends up the side of the strips?

A. Yes, sir.

X-Q. What do you mean by that?

A. Just what I said. It extends up the side of the strips.

X-Q. Is that true of the cut on the top of the page?

A. No, sir; it extends also up the side of the strip.

X-Q. And you say that the cut at the bottom of the page fourteen does not show the hub extending out between the two strips?

A. No, sir.

X-Q. It seems to me that the hub does extend between the two strips that are approximately extending towards the observer on the part that is shown are direct on the hub. Will you look again and see if that is not true?

A. That extends right up beside the strip. Your strip runs in here and your hub extends up on each edge of it at the side of the strip, but it does not extend between the strips at all.

X-Q. I think we have been using different terms and meaning the same thing. As I look at this figure on page fourteen at the bottom there was a part of the hub which projects into the angle between the two arms of the spider?

A. Into the angle at the intersection of the two arms, yes, sir.

X-Q. And in figure on page ten as I look at it there is not part of the hubs which extend into the angle between the two arms of the spider; is that true?

A. That I would say that it did because this bar here comes apparently square into the side of the hub.

X-Q. The cut on page ten is a view taken rather from the back of the hub, is it not?

A. Yes, sir.

X-Q. Now, looking at the cut at the top of page ten tell me whether the hub extends into the angle between the arms?

A. I couldn't say about that. I couldn't say whether it did or did not.

X-Q. Do you see any recess cut in the hub there to receive the arms?

A. My eyesight is too poor to see whether there is or is not a recess in there.

X-Q. In all of the cuts in the 1900 catalogue there are shown two rivets or rivet holes on the middle line of each blade. Is not that true?

A. That is, you are referring to these rivets?

X-Q. Yes, on the middle line?

A. That is, in the blades? Yes, all the cuts indicate the two rivets per fan blade.

X-Q. On the center line?

A. On the center line of the blade.

X-Q. Does this 1900 catalogue show all the types of fans put out by the Warren Company in 1900?

A. The types of fans?

X-Q. Desk fans?

A. That shows all the types that was produced at that time, that is, that season.

X-Q. On page twenty-nine of the American Electrician for April, 1901, which appears in the scrap book, is a cut of the type E-2 fan. Does that show a brass spider or the steel spider?

A. That would indicate from the place of the rivets that is a brass spider.

X-Q. How many rivets can you see on each of the blades in this picture?

A. On the upper blade I can see three rivets distinctly, on the middle blade——

X-Q. Right or left?

A. On the left middle blade there are shown two rivets placed about equal distance from the edge of the blade which would indicate there was a third rivet on that same blade. On the other two blades owing to the way the light apparently struck the blade the rivets did not show.

X-Q. Were there any fans made in 1902 with steel centers?

A. Yes, sir.

X-Q. Which ones?

A. That is, you refer now to fan motors or fan blades, you mean fan motors equipped with steel centers? Yes, the G type we equipped with those as well as other types.

X-Q. What other types?

A. Well, I couldn't say definitely, the other types that was ordinarily equipped with the brass blades and brass centers.

X-Q. They might be in type then?

A. They might be in type.

X-Q. I find a catalogue of the Colonial Fan and Motor Company which appears to be for the season of 1903. Look at the cut of the

type S-3 fan shown on page seven. How many rivets do you see on those blades?

A. I don't see any indication of any rivets at all on those blades.

X-Q. And how about the S-4 fan on page nine of the same catalogue?

A. That does not show any as far as I can see either.

X-Q. Look at the cut on page twelve of the Electrical Review for May 9, 1903, showing a Peerless fan. Do you see a rivet head on the right hand blade and lower blade?

A. No, I do not see any rivets on the right hand blade or the lower blade.

X-Q. Calling your attention to the cut of two Peerless fans in a bulletin or advertising matter of 1910 of the Peerless Electric Company. Do these cuts show steel spiders or brass?

A. Those cuts show steel spiders?

X-Q. Why?

A. They have two rivets to a blade, centrally located.

X-Q. Any other reason?

A. No, that would be the only reason I could attribute to their being steel spiders.

X-Q. Are these 1910 steel spiders of the same description as the steel spiders you say were used in 1901?

A. Yes, that would be the same type of steel spider.

X-Q. Now, in the Peerless catalogue of 1910, a copy of which I find loose in this scrap book, are the spiders shown steel or brass of the desk fans?

A. The shape of all of these spiders indicates they are stamped steel.

X-Q. Like you say you used in 1901?

A. Yes, sir.

X-Q. And they were put on the fan the same way, were they?

A. As far as I know they were. I wasn't at the Peerless Electric Company's plant in 1910.

X-Q. Did you have any steel spiders in 1900?

A. We did not.

X-Q. Or steel blades?

A. I couldn't say in reference to the steel blades. We had the dies to produce the steel blades.

X-Q. You did say on the spiders you did not have any?

A. Yes.

Redirect examination by MR. A. S. PATTISON:

Rd-Q. After the fan business of the Warren Electric and Specialty Company was taken over by the Peerless Company the latter part of 1902, please state whether your connection with the fan department continued as intimate as it was before the transfer?

A. It was not. I became general superintendent of the Peerless

Electric Company as soon as that Company was organized and devoted almost my entire attention to the development of a line of power motors and merely had a general supervision of the fan motor product with practically no time devoted to improving or further developing of the fan or fan motors.

Rd-Q. What was your title with the Warren Electric and Specialty Company before they sold their fan department to the Peerless Company?

A. I was superintendent of the fan motor department.

Rd-Q. But after the fan department was taken over what was your title with the Peerless Electric Company?

A. I was general superintendent of the Peerless Electric Company.

Defendant's counsel offers in evidence the following:

(1) Certified copy from the records of the U. S. Patent Office, extracts from the German publication entitled "Patentblatt," issue of March 14, 1906, covering title page and pages 363 and 373, and the same is marked "Defendant's Exhibit Number B-B-B-B extracts from Patentblatt of March 14, 1906."

(2) Certified copy from the records of the U. S. Patent Office of extracts from the official German publication entitled "Patentblatt," issue of June 22, 1904, covering title page and pages 863 and 867, and the same is marked "Defendant's Exhibit C-C-C-C extracts from Patentblatt issued June 22, 1904."

(3) Translation of portion of Exhibit B-B-B-B which is marked "Defendant's Exhibit D-D-D-D."

(4) Translation of portion of Exhibit C-C-C-C which is marked "Defendant's Exhibit E-E-E-E."

It is agreed that the translation is admitted subject to correction if found incorrect.

(5) A printed copy of U. S. Patent to A. M. Stanley, Assignor to General Electric Company, Number 1,176,614, dated March 21, 1916, and the same is marked "Defendant's Exhibit F-F-F-F."

It is hereby stipulated and agreed by and between counsel for the respective parties hereto that the exhibits introduced in connection with the testimony taken by way of deposition out of court or by way of deposition in open court before or during the session before Judge Killits on May 19th, 20th and 21st, 1919, if not all marked as filed, may be marked by the Clerk as filed of the said 21st day of May, 1919; and further that the depositions and exhibits introduced by either party since said last named date, if not all marked as filed may be marked by the Clerk as filed on the day of final hearing herein.

UNITED STATES PATENT OFFICE.

ELIHU THOMSON, OF LYNN, MASSACHUSETTS.

APPARATUS FOR ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 347,140, dated August 10, 1886.

Application filed March 29, 1886. Serial No. 197,077. (No model.)

To all whom it may concern:

Be it known that I, ELIHU THOMSON, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, have invented a certain new and useful Method of and Apparatus for Electric Welding, of which the following is a specification.

My invention consists in a novel art or process of and apparatus for forming joints between metal wires, bars, and the like by the agency of an electric current. This art or process I term "electric welding."

One of the chief objects of my invention is to secure a true and firm joint between metal wires, &c., without the usual necessary application of solders or metals melting at a lower temperature, and to secure a complete weld of the two abutted ends, which shall be as strong and firm as any other part of the wires, bars, &c., used.

My invention enables sections of wires—as of copper and its alloys, iron, silver, gold, &c.—to be jointed into one continuous length, and the joints, being of the metal itself nearly uniform in texture with the rest, are strong, and can be bent, twisted, hammered, and drawn without rupture—a result not achieved before my present invention.

Briefly, the new art, which I term "electric welding," consists in bringing together with a certain pressure the ends of the wires, bars, &c., to be jointed, and which pressure must be small, and can with my apparatus be regulated at will, and then constituting the abutted ends and a slight portion of the wire or bar on each side of such ends as the path for an electric current of great volume, but not necessarily of an electro-motive force of more than a few volts, (depending on the nature and size of wire or bar.) With large bars the current must be much greater than with small bars or wires, and it is well to employ as a source of current a regulable apparatus. Either continuous, intermittent, or alternating currents of electricity may be employed.

I will now proceed to describe, by reference to figures, the manner in which I have practiced the process and the apparatus which I have found suitable therefor.

Figure 1 shows my jointing-clamp with wires ready to be electrically welded. Fig. 2 is another view of a portion of the same. Fig. 3 shows the placing of wire or bars in line in the clamps before abutting the ends for welding. Fig. 4 shows a joint just formed, there being usually a slight burr or flange formed at the junction after passage of current. Fig. 5 shows removable clamps for holding wires of varying sizes. Fig. 6 shows a clamp for holding wires of three sizes as needed. Fig. 7 indicates the substitution of manual pressure for elastic pressure in forming the joint. Fig. 8 indicates the substitution of gravity for elastic pressure in forming the joint; Fig. 9, a modification of the same. Figs. 10, 11, 12, 13, 14, and 15 indicate the application of my process to other forms of bar, &c. Fig. 16 illustrates one of the ways of generating the heavy currents needed in the practice of my invention. Fig. 17 illustrates a modification of a portion of Fig. 16. Fig. 18 shows another way of obtaining currents of sufficient volume for practicing my invention.

I reserve for other applications for Letters Patent certain other improvements in the apparatus used in practice.

In Fig. 1 is shown the apparatus applicable to the case of joining ends of wires, &c. It consists of two arms or clamp-holding bars, L L', one only of which need be movable. This is swung on a joint at A, which, when the arms L L' are wholly metallic, is insulated by interposed washers and tube of insulating material, as mica, in a way to allow the free movement at A, but no passage of current at such point. Heavy cables C C', preferably very many times the section of the wires to be jointed, connect L L', respectively, with the terminals of apparatus, from which, at will, a sudden flow of current of considerable volume may be obtained. Suitable clamps, K K', (this latter, K', shown removed,) serve to bind down firmly and make good electrical contact with a portion of the length of the wires to be jointed. The wires W W'—say of copper, brass, iron, steel, or German silver—are placed in the clamps with their ends abutting and projecting, as shown at J, the edges of the clamps being countersunk or rounded, so as to leave a small portion of W and W' unclamped near J. An adjustable spring, S, arranged to pull L L' together, but insulated by an interposed block of insulator I, is used to

1024

keep the wires W W' abutted with a slight pressure. I sometimes provide a set of heavy copper contacts, Z Z', which automatically connect L L' after the joint at J is effected, accompanied, as it is, by the slight approach of the parts L L' under the action of the spring S when the metal at J welds.

Fig. 2 shows one leg, L', removed and the remaining one, L, seen from between them, showing opening for wire and insulation of joint A in black.

Fig. 3 shows wires W W' just before abutment together with their relation to the clamps K K'. When in contact, as in Fig. 1, a powerful current is passed from C to C', which current has to pass the abutted ends at J. However, if of great volume, even though the resistance at J be less than one fifty-thousandth of an ohm for very moderate-sized wires, heat will be developed in the ratio of the square of the current flowing, which heat will be formed at J in sufficient amount to fuse the abutted ends, and under slight pressure they will weld over their whole section with a slight projecting burr or expansion, as indicated at J, Fig. 4. This will be seen to occur by the slight yielding at J and the approach of L L' toward each other by the elastic force of S. The current is then stopped and the clamps removed, and the wires W W' will now be found united into one. The burr can be readily filed off or ground off, and if the clamps K K' were set oppositely at the start the joint will be true with the axis of each wire. Of course it is important that the wires shall be clean to insure contact, and though usually the joint is well formed without any flux, such as borax, there is no objection to its use in slight amount in certain cases. In such cases, after abutting the wires, a little moist powdered borax or other flux may be applied at J. The clamps for holding the wires may be made removable shells, so as to be readily substituted when different sizes of wire are to be clamped, although simple V-grooves may be made in the clamps to accommodate various sizes; or universal chucks may be employed. All such variations are without importance, and are evident to mechanics.

Fig. 5 shows removable clamps, and Fig. 6 a compound clamp with three sets of grooves of different sizes.

In Fig. 7 the spring S, Fig. 1, is left off, and is replaced by handles, which may be manually pressed together in forming the joint. A little practice will show the pressure to be used in each case.

In Fig. 8 an adjustable weight, P, sliding on L', extended, which latter may be graduated, forms an efficient substitute for S, Fig. 1, the other parts being suitably disposed.

Instead of using a swinging joint, as A, Fig. 1, it is sometimes preferable, as where heavy wires are to be accurately abutted and jointed, that the movable piece L shall slide in guides, giving a rectilinear motion, though equivalent parallel or right-line movements may be attained in other well-known ways.

The clamps K K' can be shaped to suit various forms of wires or bars to be joined—such as square, hexagonal, rectangular, &c.—and it will be evident that tubes can be operated upon instead of bars or wires.

Fig. 10 shows two rectangular bars prepared for juncture.

Fig. 11 shows how my invention may be employed to effect joints between pieces of different form, W' in the figure being a flanged head. In this connection it may be remarked that my invention gives a great advantage in permitting the formation of joints without heating the metal to any considerable distance on each side of the joint, so that temper, elasticity, and finish remains uninjured.

Fig. 12 illustrates the union of a rectangular bar to a round bar. It may be here said that in all cases it is best that the clamps for holding the pieces be fitted to the shape of the pieces, and clamp them quite near the junction. In such way even rings, as in Fig. 13, may be rendered endless; but in this case more current is needed, as a portion passes around the ring; but, further, on account of the greater length, it is small compared with the portion traversing the joint when the clear ends are well abutted and the clamps K K' embrace the ring, as indicated. In Fig. 13 the lower part of the ring B can, if needful, be immersed in water to avoid any chance of heating.

In Fig. 14 a long bar or wire of metal or a band can be made endless, as in Fig. 13, and I propose to apply my invention to the production of endless steel pieces for band-saws and the like, and so to remove the weaker brazed joint and the consequent destruction of temper near where it is made. My invention can also be applied to the production of endless wires for endless twisted cables, and it may also be used to join the separate ends of the wires of a twisted cable and so make the cable endless. It is also possible to join two smaller pieces to one larger piece, as in Fig. 15.

To insure success in effecting a joint the parts opposed should, if possible, be of the same section or at least of such dimensions and melting-points as to melt nearly at the same time, and so secure a thorough union of the particles of both pieces. However, junction is easily effected between German silver and steel or iron and between brass and iron, and in many other cases where the metals joined differ.

As an example of a means of securing a large flow of current with little electro-motive force, such as is demanded by my invention, the arrangement shown in Fig. 16 is used. In this case an induction-coil consisting of a core, F, of iron wire wound with two windings is employed. One of the windings is of fine wire, M, and connected into a circuit by

plying alternating currents suited to the size wire in M, while a simple switch, B, controls the circuit through M. The other winding, N, is a very few turns of very heavy conductor connected by short and thick connections to the wire-jointing clamps L L', as in Fig. 1. When all is ready to make a joint, the switch B is closed for a second or two, at which time the currents in N will be induced, and since the resistance of the wires to be joined will be a large fraction of the actual resistance in the secondary circuit, so a large portion of the energy will be evolved where the joint is to be made, incipient fusion will result and subsequent thorough welding. To save parts it may be simpler to give the coil N the disposition indicated in Fig. 17 by attaching L L' to its terminals, and having the terminals possess a slight elasticity toward one another, so as to give the pressure needed to make the joint.

In Fig. 18 is illustrated the employment of a cell of secondary battery as a source of current. It need only be a plain Planté battery of large surface, so as to yield, on occasion, many thousands of amperes, according to the diameter and the conducting-power of the wires to be joined. It is charged by being placed in a circuit, *a b*, of moderate current-supply, such as an arc or other line.

The heavy conductors L L', one from each terminal of the battery, are ordinarily sprung apart and insulated, as at I. When the wires W W' are in place, they are kept out of contact until the charge of the battery is sufficient to give a flow of current of a few seconds duration, at which time the handles H H' are pushed nearer together, thus effecting contact, fusion, and welding between the ends of the wires W W'.

Other sources of electricity may be used, such as currents from large dynamos, either direct current or alternating in character.

Instead of employing the pressure of a spring, or gravity, or manual pressure to effect the welding, I may obviously employ pressure obtained from any other source.

What I claim as my invention is—

1. The herein-described art of effecting union between two pieces of metal, consisting in holding the same in contact at the point of union and simultaneously passing a current of electricity through the joint of a power to fuse and unite the pieces, as and for the purpose described.

2. The process or art of electric welding, consisting in the application of heavy currents to traverse a joint to be welded, and the simultaneous application of a pressure or force tending to move together the pieces to be welded.

3. The process or art of causing union between the ends of metal pieces in contact by simultaneous application of fusing-currents of electricity and mechanical pressure at the contact.

4. In an apparatus for electric jointing of metals, suitable clamps for holding the pieces to be joined movable toward one another, and means, such as a spring, for exerting a pressure for forcing the pieces into contact, and means of applying fusing-currents of electricity while such pieces rest in pressure contact, as described.

5. The combination, in an apparatus for electric welding, of two arms or supports, L L', connected with a source of electric current, removable dies or holding-clamps carried by said arms, and means whereby said arms may be pressed toward one another, as and for the purpose described.

6. The combination, in an apparatus for electric welding, of clamps or holders for grasping the pieces to be welded, connections from said clamps to a suitable source of electric current, and an adjustable spring, or its equivalent, as described, for adjusting the force with which the pieces are pressed toward one another during the operation of welding.

7. In an apparatus for electric jointing of metal wires, bars, &c., a primary feeding-line connected to any suitable source of current and controlled by a switch, and a secondary fusing or welding circuit connected to the pieces to be welded, and which are held in pressure contact, together with suitable means of transfer of energy from said primary line to the circuit of the fusing or welding apparatus, as described.

8. The art or process of electric welding, consisting in applying to suitably guided and clamped pieces to be joined a powerful electric current at the junction simultaneously with a pressure, whereby upon incipient fusion at the joint a complete union is effected.

ELIHU THOMSON, OF LYNN, MASSACHUSETTS.

APPARATUS FOR ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 347,141, dated August 10, 1886.

Application filed March 20, 1886. Serial No. 195,994. (No model.)

To all whom it may concern:

Be it known that I, ELIHU THOMSON, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, have invented a certain new and useful Apparatus for Electric Welding, of which the following is a specification.

My invention relates to an improved apparatus for the practice of a new process or art of welding by electricity, which forms the subject of a separate application for patent.

The object of my invention is to facilitate the operation and provide for its control.

It consists of a regulable source of current provided with an induction apparatus, to be presently described, and also of a means for easily clamping the pieces to be welded and of setting them in position.

Figure 1 shows my improved apparatus; Fig. 2, a clamp for quick work in clamping and unclamping pieces to be joined and that have been joined or welded. Fig. 3 shows the form of one of the removable clamping-blocks for wire; Fig. 4, another view of the same; Fig. 5, a stop for insuring proper placing of the pieces to be jointed. Fig. 6 is another view of the same. Fig. 7 is one example of the work that can be accomplished. Fig. 8 shows another example of the same.

A B, Fig. 1, are wires leading from a source of alternating electric currents to the coil of insulated wire P, wound around a ring-shaped iron core, F F, as shown. The coil P has a number of turns, depending on the electro-motive force and current supplied to it, its convolutions being usually numerous when used with average electro-motive forces and current-strength. The connections of A and B to P is made so that a variable resistance, R, (or the equivalent may be substituted for it,) may be inserted in greater or less amount, so as to vary the force of the primary circuit-current in the coil P, and the switch Z permits of rupturing such circuit at will. Around the same iron core F F are also wound a few turns of heavy copper cable S, giving an almost inappreciable electrical resistance. The ends of the secondary coil are attached each to one of a pair of clamp-bearing arms or blocks, L L', of good conducting metal, relatively placed and guided so as to have only a slight movement toward and from each other. For such purpose an insulated flexible plate, as at G, may be used in conjunction with an insulated pillar borne by L at E, and passing through a hole in L'. A nut, N, and compressed spring S strung on said pillar permit said pillar to be used for drawing arms L L' toward each other with a pressure depending on the position of the nut N. The clamps K K' are placed opposite one another on arms L L', respectively, and a screw, H, serves as needed to force arms L L' apart and hold them so separated. The clamps K K' are made so as to hold in place the replaceable divided dies or sleeves for holding wires or other pieces near the point of welding or juncture.

In order to manipulate the clamps rapidly, they are preferably made as in Fig. 2, where the body K is hinged to L, and the free end arranged to be set or clamped by a movable clamp-screw in a swinging frame, D, as shown.

The dotted lines show the parts contained. The removable parts surrounding the wire or bar to be welded are like Figs. 3 and 4, and are made of copper or other good conductor in halves, the size of interval bore being nearly equal to the dimensions of the bar to be clamped, and such bore is somewhat countersunk, preferably at the end where the wires, W W', to be jointed are abutted at J, Fig. 1. The wires or bars W W' should be set projecting a little from the clamp-blocks when abutted, and to secure this I have devised a stop-plate, O, Fig. 5, for insertion between the clamping-blocks K K', as indicated, such plate O having a thin portion against which the wires may be abutted, and a thicker portion immediately above for insertion between the clamp-blocks, so as to determine their distance apart during the insertion of the wire. The removal of O leaves the wires free to abut and yet project some little distance from the clamps.

Fig. 6 shows the stop-plate O on its flat side, while in Fig. 5 it is seen edgewise.

The operation of my apparatus is as follows: The wires or bars W W', of iron, steel, German silver, brass, copper or its alloys, &c., having been inserted into the clamps by the aid of the plate O or without it, and the screw H, Fig. 1, turned back, so as not to in-

nates with the approach of L L', under the action of the spring under the nut N, the which I is momentarily closed to permit alternating currents to flow in coil F. There results very heavy currents in S, which traverse the junction or electrical ends of W W', projecting from the clamps. The locomotive result in partial fusion of such ends and unites into one piece by the force of the spring under I. Suitable adjustments of current and clamping pressure are readily made to suit the size of bars or wires and their conducting power, so as to fuse or electrically weld them. Joints of steel with steel or iron are thus easily formed, or with German silver or brass, or of brass with brass, or with iron, steel, or German silver, &c.

Other means of regulating the current given out by S may be used, some of which are indicated in Figs. 9, 10, 11, 12, and 13.

In Fig. 9 the iron core F is divided, and one portion is made movable toward and from the other, so as to more or less completely close the magnetic circuit of the core by a regulating screw, N', or the like.

In Fig. 10 the core has another coil, F', wound on it, in the circuit of which a variable resistance, R, may be inserted or cooled. This coil F', when on short circuit, will nearly annul F in any effect in S, but when on open circuit will give to S its full power, and with varying resistance in its circuit the current induced in S will vary. Its effect is similar to placing a closed tube of copper of greater or less dimensions around the core or parallel to the secondary S.

In Fig. 11 the core F is made movable to and out of the axis of S, to vary the current generating inductive currents in S.

In Figs. 12 and 13 the core F is surrounded by the primary coil P, as shown, and is of such diameter that a single band of copper, S, also forms the secondary, and whose position as regards the coil P and core F may be changed from the maximum position shown to any other. In this case the halves of the band S may also replace the arms L L' by hinging them, as shown, and providing a fastening and connection or shunt, C, around the hinge-joint. The wires W W', or bars to be joined, are held clamped by clamp-screws, and are pressed together by an adjustable elastic spring, Y, which is prevented from making connection between the separated ends of the band S by insulation, as at R.

Other methods of regulating the discharge of currents may be used, and my invention is not limited to such particulars.

What I claim as my invention is—

1. In an apparatus for electric jointing or welding, a source of heavy currents and means for regulating the same, in combination with devices for holding the pieces to be welded, and with a means of impressing a pressure resulting in force such pieces together.

2. In an apparatus for electric jointing or welding, the combination, with devices for holding pieces to be welded, of a coil wound upon an iron core and connected with a source of electricity, a secondary coil or circuit of low resistance, connections from said secondary coil to the holding devices, and means for varying the magnetic inductive effects of the core upon the secondary, as and for the purpose described.

3. In an apparatus for electric jointing or welding, the combination, with devices for holding the pieces to be welded, of an inductorium apparatus wound with two coils, one of low resistance as compared with the other, connections from the low resistance coil to the holding devices, and a source of electric currents connected with the coil of comparatively high resistance.

4. The combination, with the clamping blocks and means for connecting the same with a source of electricity, of a coil placed, (1,) having a fixed position, against which the parts to be welded may be abutted, and a movable position, against which the clamp-blocks may abut, so as to determine their distance apart in the operation of inserting parts to be welded.

5. In an apparatus for electric welding, a regulable source of current of electricity and means of passing the same through the pieces to be welded and across their surfaces of contact, in combination with means for exerting a regulable pressure upon such surfaces, as described.

6. An apparatus for electric welding, consisting of a primary coil fed by alternating currents, means for regulating the effect of said currents upon the secondary coil to indefinite relative extents, clamps for holding the pieces to be joined, to act in contact with each other at the point of junction, and means for pressing said pieces together at the point of junction, as described.

UNITED STATES PATENT OFFICE.

NICHOLAS DE BENARDOS AND STANISLAS OLSZEWSKI, OF ST. PETERSBURG, RUSSIA.

PROCESS OF AND APPARATUS FOR WORKING METALS BY THE DIRECT APPLICATION OF THE ELECTRIC CURRENT.

SPECIFICATION forming part of Letters Patent No. 363,320, dated May 17, 1887.

Application filed December 3, 1885. Serial No. 184,575. (No model.) Patented in France October 10, 1885, No. 171,596; in Belgium October 20, 1885, No. 70,569; in England October 21, 1885, No. 12,984; in Germany November 1, 1885, No. 38,011; in Sweden November 6, 1885, No. 726; in Russia December 31, 1886, No. 11,982, and in Spain January 5, 1887, No. 10,267.

To all whom it may concern:

Be it known that we, NICHOLAS DE BENARDOS and STANISLAS OLSZEWSKI, of St. Petersburg, in the Empire of Russia, have invented certain new and useful Improvements in the Process of and Apparatus for Working Metals by the Direct Application of the Electric Current, (for which we have obtained patents as follows: in France, No. 171,596, dated October 10, 1885; in Belgium, No. 70,569, dated October 20, 1885; in England, No. 12,984, dated October 21, 1885; in Russia, No. 11,982, dated December 31, 1886; in Sweden, No. 726, dated November 6, 1885; in Spain, No. 10,267, dated January 5, 1887, and in Germany, No. 38,011, dated November 1, 1885,) of which the following is a specification.

Our invention contemplates the formation or production of the voltaic arc between the metal to be operated on and a conductor which is brought for said purpose into proper proximity to that point on the metal which is to be operated on, the conductor forming one pole, while the metal to be worked constitutes in itself the other pole. In other words, the metal to be worked and the conductor extraneous to said metal constitute two electrodes or terminals, by the approach of which to each other the circuit in which both are included can be completed through the voltaic arc produced between them. It is this feature which mainly characterizes our invention, and which differentiates it from other methods which have been proposed of working or melting metals by the electric current.

The advantages attending our invention are, briefly stated, its simplicity and efficiency, as well as its wide range of application in the industrial arts.

The only apparatus needed to put this invention into practice outside of the electrical generator or source of electrica supply, and the circuit leading therefrom to the metal to be worked and to the extraneous conductor, is a holder for the said conductor, the holder and the metal to be operated on being so arranged as to be movable relatively to each other, so as to bring the conductor opposite to any desired point on the metal. We prefer, usually, to move the conductor-holder over the metal. The conductor preferably consists of a stick or cylindrical rod of carbon. The form and material of said conductor, however, are not essential features.

In the accompanying drawings we have shown some forms of apparatus, which we will now proceed to describe, in order to more fully explain the manner in which our process can be practically applied

Figure 1 is a side elevation, partly in section, of a simple form of carbon-holder. Fig. 2 is a like view of a holder adapted to rest upon and be moved over the face of the metal plate or plates which are to be operated on. Fig. 3 is a side elevation of a modified form of apparatus. Fig. 4 is a section on line 4 4, Fig. 3. Fig. 5 is a section on line 5 5, Fig. 3. Fig. 6 is a plan of the rails on which the holder shown in Fig. 3 is mounted. Fig. 7 is a side elevation of a form of apparatus in which the carbon is stationary and the metal to be operated on is movable under the carbon. Figs. 8 to 21 represent various applications of the invention or uses to which it may be put.

The holder shown in Fig. 1 consists of a wooden or other non-conducting handle, A, having in its rear end a socket and binding-screw, B, electrically connected to the conducting stem or shank G, to which is jointed or hinged at H a sleeve, E, containing the carbon pencil D, held in place therein by clamp-screw F. The binding-screw B serves to hold in place the metallic conductor C, which leads from one pole (usually and preferably the + pole) of the source of electricity. The other pole of said source of electricity is connected to the metal to be operated on. When the carbon D, under these conditions, is brought into proximity to the metal to be operated on, the voltaic arc will be produced between the two, with the effect of heating, softening, and finally melting the metal at the point where the arc meets it. The holder can be moved over the metal from one point to another to

act on it in a continuous line, or at separate points, as desired.

The apparatus shown in operation in Fig. 2 consists, also, of a wooden handle, A, with a metallic socket and binding-screw, B, at its rear end, metallic shank G, jointed sleeve E, clamp-screw F, and carbon pencil D, as in the preceding figure. Handle A has a flat base, A', which rests upon and can move over the two metal plates *r r'* to be operated on. The conductor C for the carbon leads from the + pole of battery X, (typical of any source of electricity, such as accumulator, battery, or dynamo,) and the other pole of said battery is electrically connected to said plates *r r'*, as shown.

The stem G is a two-part stem jointed together at *x*, and its front end, G', is continued back of the joint in the form of a lever, G', which extends under the handle A. A spring, K, keeps the part G', and consequently the carbon D, lifted, thus maintaining a normally-open circuit. By pressing lever G' toward the handle the carbon can be lowered into proper proximity to the plates *r r'* to produce between it and them the voltaic arc. In this figure the apparatus is shown in operation uniting the two plates by a process akin to riveting. By the action of the voltaic arc the metal is gradually melted, the fusion extending through into both plates, the melted portions of which are mingled together, so that when the same cool the two plates, as to said fused portions, are virtually in one homogeneous piece.

The apparatus shown in Figs. 3, 4, 5 in the main resembles that illustrated in Fig. 2. Its base is provided with front and rear pairs of flanged wheels, which run upon either one of two pairs of rails, L L', on a track-frame, M. The rails L are cogged or toothed, as shown, and are designed to be used when the holder is employed for what may be termed "point-union"—that is to say, for operating on the metal at points whose distances from one another will be equal to the distance intervening between the teeth of the rails. The other rails, L', are ordinary straight smooth rails, and are to be used when the holder is employed for uninterrupted or continuous union. This holder is provided with a screen, N, of colored glass, attached to the holder by a universal joint at O, which will permit it to be set in any position required, in order to shield the eyes of the operator from the injurious effects of the voltaic arc. It is also provided with a secondometer or other suitable time-piece, P, having a stop-lever, *a*, connected to and arranged to be operated by an arm, *b*, attached to the handle end of vibratory stem G. Normally the handle end G' is depressed by its spring, thus lifting the carbon and breaking the circuit, and the parts are so adjusted that in this position the arm *b* will bring the stop lever to position to stop the time-piece When, however, the handle is pressed upward, thus bringing the carbon into action, the stop-lever will be moved in a direction to permit the time-piece to start. In this way the duration of the operation, in the case of point-union particularly, can be accurately determined.

It will be of course understood that, instead of connecting the wire from one pole of the battery directly to the metal to be operated on, it can be connected to a metallic plate or stand, which serves as a working-bench to support the metal operated on, the two being of course in electrical contact. Such arrangement is represented in Fig. 7, the apparatus being designed for use as a forge. The stand R is furnished with a grooved guide-pulley, *c*, which receives and supports the metal tangs or shanks of pinchers S, whose handles are sheathed with wood or other insulating material. The pinchers are in electrical contact with the metal pulley, over which they can move to bring the article held by them (in this instance supposed to be a chain-link) under the carbon, which is supported in a stationary holder. The circuit-connections are the same in the other figures. The metal to be operated on can in this apparatus be heated to the desired extent, and then can be transferred to the usual anvil and forged in the customary way.

Our invention, as hereinbefore indicated, is susceptible of a wide range of application. It can be used, for instance, for joining metals whether end to end or placed one on top of the other, for making holes in metal, or for dividing a piece of metal into two or more parts, for steelifying, and for numerous other purposes.

Figs. 8 to 19 represent some of the ways in which metals may be joined by our invention. These figures require no explanation, further than to say that the darkened points or lines in them indicate where the metal has been operated on.

Fig. 20 illustrates the manner in which holes may be bored in metals.

Fig. 21 represents a metallic plate having pattern of fused metal incrusted thereon. The plate is heated to the temperature of fusion at the point where the extraneous metal is to be applied, and said metal in fused condition is dropped upon the heated point or points, thus forming a metal incrustation, which enters and becomes part of the plate. In this way we can incorporate into the plate other metals, granite, porcelain, &c.

From the foregoing it will be observed that the essence of our invention is that the metal itself at the point where it is operated on becomes one pole of the voltaic arc, while the carbon or other extraneous conductor approached thereto constitutes the other pole.

Having now described our invention and the best way at present known to us of carrying the same into effect, what we claim, and desire to secure by Letters Patent, is as follows:

1. The improvement in the art of joining or

separating metals by means of the directly-applied electric current, which consists in forming the voltaic arc at the desired point or points, or along the desired line or lines, on said metal by a conductor approached thereto, which constitutes one pole, while the metal itself constitutes the other pole, as and for the purposes hereinbefore set forth.

2. The process of topically working plates, blocks, or other solid masses of metal, which consists in forming the voltaic arc at those points only of the metal which are to be worked, (leaving the other portions of the same unaffected,) through the agency of an extraneous conductor, which constitutes one pole, while the metal itself constitutes the other pole, as and for the purposes hereinbefore set forth.

3. The carbon-carriage consisting of a frame adapted to rest on and move over the face of the metal to be worked, a carbon or other conductor, a holder therefor carried by said frame and movable to and from the metal on which the frame rests, and means whereby said holder can be actuated, at will, to cause the carbon to approach or recede from the said metal, substantially as hereinbefore set forth.

4. The combination of the supporting-frame, the carbon-holder carried by and movable and adjustable on said frame, and the time-piece connected with and operated by said holder at the times and in the manner substantially as and for the purposes hereinbefore set forth.

In testimony whereof we affix our signatures in presence of two witnesses.

ELIHU THOMSON, OF LYNN, MASSACHUSETTS.

METHOD OF ELECTRIC RIVETING.

SPECIFICATION forming part of Letters Patent No. 396,015, dated January 8, 1889.

Application filed October 12, 1888. Serial No. 287,910. (No model.)

To all whom it may concern:

Be it known that I, ELIHU THOMSON, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, have invented a certain new and useful Improved Method of Electric Riveting, of which the following is a specification.

My invention consists, essentially, in a method of riveting by placing the rivet or rivet-blank in position in the socket or hole designed to receive it, passing through said rivet an electric current of sufficient volume to heat the same to the requisite temperature, and then setting the rivet in its position by endwise pressure or other means employed in ordinary riveting operations.

In carrying out my invention I may swage or form both heads after the heating of the rivet-blank in position in the work, or may swage or form one head only, the rivet having been inserted with one head ready formed. The heating of the rivet when in position may be carried only to the point sufficient to permit it to be set by swaging or heading its ends, or the current may be allowed to pass for a longer period and until the central portion of the rivet, as well as the metal near thereto, is raised to a welding temperature, when the application of pressure expanding the rivet in its seat will weld the same to the metal surrounding it, and the application of pressure to the pieces to be riveted will weld them together around the rivet. In some cases I may cause the electric current to flow across from piece to piece of the parts to be riveted, as well as through the rivet itself.

Detail processes forming a part of my invention will be more particularly specified in the claims.

In the accompanying drawings, forming a part of this specification, Figure 1 is a side elevation and partial section of a form of apparatus suitable for carrying out my method of electric riveting. Fig. 2 is a view of the rivet after the operation has been effected. Figs. 3 and 4 illustrate modifications in the manner of practicing the invention. Figs. 5, 6, 7, and 8 are illustrations of the work accomplished. Fig. 9 is a side elevation of an improved form of apparatus which may be used in practicing my present invention. Fig. 10 shows a further modification.

In Fig. 1, P P' indicate two plates of metal—such as boiler or sheet metal—to be secured together by means of a rivet placed in a hole passing through lapped portions of the plates.

C C' indicate two blocks or pieces of material adapted to conduct an electric current and made sufficiently massive to permit the current of large volume required in the operation to pass without becoming unduly heated.

The electric current required is conveyed from any source—such, for instance, as that described in my previous patent, No. 347,140—to the blocks C C' by means of cables D D', or by other means, and the blocks are insulated from one another, as indicated at I, in order to prevent the current of the cables from short-circuiting around the work. Supported upon the head S of the block C', and in electrical connection therewith, is a plunger G, whose end is of the nature of a swaging tool or die, and which may be forced against the work by means of a screw, W. Formed upon or attached to the block C, and in electrical connection with the source of current, is another receiving block or anvil, E', for one end of the rivet. The faces or ends of the blocks G E' are in line with one another, and are adapted to receive the rivet R between them. The contour of their swaging, forming, or holding ends may be considerably varied, according to the special manner of securing the rivet in place which it is desired to employ. In the form shown in Fig. 1 the end of G is made concave to receive and fit over the end of the rivet-blank and to operate as a means of swaging a head upon the rivet-blank. The other block, E', is similarly formed for a similar purpose.

In employing the apparatus described the blocks or pieces G E' are brought to bear upon the rivet or rivet-blank R, which has been previously inserted into the hole through the plates, the ends of said blocks receiving the ends of the rivet or rivet-blank between them. Electric current is now turned on and made to pass through the rivet or blank in sufficient volume to heat the rivet to a softened condition, after which endwise pressure or other force is applied through the plunger G—as, for instance, by means of screw W. This will firmly seat and expand the rivet in

10339

its hole, and will at the same time form heads at opposite ends of the rivet-blank, or at one end thereof only, if, as indicated in Fig. 3, a rivet with a head already formed has been inserted into the hole previously to the riveting operation.

Fig. 2 illustrates the condition of things at the completion of the operation, the rivet being there shown as set.

In Fig. 3 the rivet is shown as having one head formed on it before being inserted into the hole bored or punched for the purpose. The other head is formed at E' by the movement of the clamping piece or plunger G' after the current has heated the metal to the desired temperature.

Fig. 4 simply illustrates the fact that two plungers, G G', might be employed and moved in opposite directions or toward the rivet-blank R after the blank is sufficiently heated. This figure also shows that the holes punched or bored in the plates may be countersunk, so that the riveted heads may not protrude from the plates.

Fig. 5 shows two plates riveted in this manner, the rivet fitting solidly into the countersunk holes, as shown at *h h'*.

A valuable effect, (illustrated in Fig. 6,) not possible in other processes, may be obtained in my method of riveting by continuing the heating of the rivet-blank placed in the hole for some moments longer than is necessary to raise it to a softening temperature. By continuing the heat is carried to the portions of the plate surrounding the rivet, raising such portions to a welding temperature, and when the rivet is pushed firmly into the hole a partial welding of the rivet to the sides of the hole is effected, thus forming practically solid metal for a portion of the distance from *h* to *h'*.

Fig. 7 shows a similar effect, which occurs when the rivet-heads are not forced into countersunk holes, but are allowed to protrude from the plates.

Fig. 8 shows a modification where one head of the rivet is allowed to protrude from the plate, the other end fitting solidly and evenly into the countersunk hole bored to receive it.

Fig. 9 shows a modified form of apparatus which is found useful in carrying out my improved method of electric riveting, and which is an improvement over that of Fig. 1, inasmuch as it can be used to force the plates together before the current is put on and keep them together while the rivet is heated and secured in place. K K' are heavy clamping-pieces having a common bed or support, B', and one or both provided with a screw, S'. By means of screw S' the clamping device K K' may be forced hard against the plates P P', as shown in the figure, thus making a firm contact where the metals are lapped over each other.

The plungers or formers G G' are mounted in the clamp-heads, and are operated by means of the screw-nuts X X' bearing upon levers connected to the plungers. By the use of this form of apparatus a heating electric current might be passed through the metal plates themselves at parts around the rivet by means of the pressure pieces or clamps K K'. Such current would assist in raising the portion of the plates immediately surrounding the rivet to the welding temperature; but the prime object is that through the application of the pressure the plates themselves may be held together during the riveting. The blocks K' K may therefore be faced with mica or other insulator, *m m'*.

Fig. 10 shows a modification of the just-described apparatus. G is one of the plungers which is used to convey the current to the rivet R. K^2 is a heavy piece of metal, so arranged as to press against the plates P P'. Pressure is applied to piece K^2 from the plunger by the springs *s s*.

It will be seen that by my improved method of electric riveting a large amount of labor is overcome and much time is saved. The heating of the rivet can be accomplished in a very few seconds, the time depending on the power of the electric apparatus supplying the current. It is also obvious that the inconvenience of transporting hot rivets from the forge to the hole in the boiler or other plates is avoided in my present invention. The superior advantage, also, of partially welding the rivet to the plate is obvious.

I have described some of the forms of apparatus that may be used for carrying out my invention; but it will be readily understood that the same method might be practiced by using other devices.

While I have described the riveting of the blank after heating as being performed by means of the blocks through which current is applied to the rivet or blank, it is obvious that the invention might be practiced by withdrawing said blocks after the rivet has been heated to the desired degree, or by applying the current through any other means, and then heading the rivets by any desired means.

I have not herein claimed the apparatus described, as my present patent is for the novel art or process, whether practiced by means of the apparatus described or any other suitable apparatus.

What I claim as my invention is—

1. The herein-described improved method of riveting, consisting in heating the rivet or rivet-blank electrically while in place, and then heading either or both ends of the same.

2. The herein-described method or process of riveting, consisting in making the rivet while in position a portion of a circuit carrying a heating or large volume of electric current, and then setting the rivet by any desired means, as and for the purpose described.

3. The herein-described method of riveting, consisting in passing a heavy electric current through the rivet or rivet-blank while the

same is in position, and then applying end-pressure to the rivet to set the same.

4. The herein-described method of riveting, consisting in applying to opposite ends of the rivet while in position suitable metal blocks or pieces, either or both movable, including said blocks and rivet in an electric circuit carrying an electric current of large volume for the purpose of heating the rivet, and then forcing said blocks or pieces toward one another to set the rivet.

5. The herein-described method of riveting, consisting in heating the rivet while in place by an electric current until it assumes a welding temperature, and then applying pressure to set the rivet in its seat and unite the sides of the same to the metal body through which it passes.

6. The herein-described method of fastening two pieces of metal together, consisting in passing a heating electric current throu a rivet or rivet-blank, passing through t pieces as well as through the pieces of met themselves in the neighborhood of the rive and applying pressure to set the rivet a weld the pieces together.

7. The herein-described method of electr riveting, consisting in pressing the plates t gether, heating the rivet inserted through t plates by a heavy electric current flowin through the same, and applying end-pressu to the rivet to head or set the same.

Signed at Lynn, in the county of Ess and State of Massachusetts, this 10th day October, A. D. 1888.

UNITED STATES PATENT OFFICE.

MARK W. DEWEY, OF SYRACUSE, NEW YORK, ASSIGNOR TO THE [illegible] CORPORATION, OF SAME PLACE.

METHOD OF ELECTRIC RIVETING.

SPECIFICATION forming part of Letters Patent No. 620,727, dated July 28, 1899.

Application filed April 24, 1899. Serial No. 714,271. (No model.)

To all whom it may concern:

Be it known that I, MARK W. DEWEY, of Syracuse, in the county of Onondaga, in the State of New York, have invented new and useful Improvements in Method of Electric Riveting, (Case No. 57,) of which the following, taken in connection with the accompanying drawings, is a full, clear, and exact description.

My invention relates to electric riveting, and is a method or process consisting, essentially, in interposing insulating material between the pieces or plates to be riveted together, then inserting the rivet into the rivet hole or holes, and then passing a heating electric current through and between the plates and rivet.

The object of my invention is to confine the current in its passage between the metal blocks or riveting-tools forming the terminals of an electric circuit to the rivet and metal body through which it passes, or, in other words, to direct or guide the current in a certain path through the work that will tend to produce more effective and economical results than heretofore.

In the usual methods of electric riveting heretofore employed the metal pieces or plates to be riveted together were laid one upon the other without insulating material between them, and then punched or drilled and the metallic rivet inserted in the rivet hole or holes. The metal blocks or terminals of an electric circuit were then brought into contact with the ends of the rivet and the current allowed to pass through said rivet and plates until the ends of the rivet were sufficiently softened, when it ceased by pressure applied to its ends to form heads. The rivet was in direct contact with the electric terminals, and also with the plates through which it extended, and the current in its passage between the terminals naturally expanded and divided when it reached the plates, except at the projecting ends of the rivet in contact with the terminals. The ends alone of the rivet, therefore, were sufficiently heated, and the portion of the rivet-shank within the holes in the plates remained comparatively cool, as it received but a small part of the current and did not become properly welded or united to the walls of the rivet-hole. Consequently it was very common to form heads on the ends of the rivets by pressure in order to secure the plates together. It will be seen that a large part of the current was wasted by this method, especially when it was desired to unite the ends of the rivet to the metal body through which it passed, as the current had to pass through the work a long time. It is essential that the riveting operation be done as quickly as possible; otherwise, as the plates have usually good radiating surfaces and good conductivity, the heated will be rapidly dissipated as wasted.

It will be apparent from the above that heretofore an electric riveting operation depended largely upon the resistance derived by the ends of the rivet, as the portion within the hole, with the metal body surrounding and in contact with it, formed a path for the current of very low resistance, which became heated, if heated at all, only by the conduction of heat from the highly-heated ends of the rivet. By my improved method I confine the current passing between the metal blocks forming the terminals of the circuit, to a path of high resistance, so that the rivet-shank within the hole and the walls of the hole are both raised to a welding temperature at or completely united. The expansion of the rivet-shank and the metal body surrounding it, produced by the heat of the current, allows sufficient to effect the union of the parts without pressure of any kind. Nevertheless, if desired, suitable pressure may be applied also, as when a heading operation is required. A heading operation is not necessary with my process, as the rivet is firmly welded to the metal body or plates throughout its length and they become one piece, thus saving of heading and countersinking.

It has been proposed, in order to confine the current to the rivet, to cover the rivet-shank with insulating material, but this effectually prevents the union of the rivet with the metal body, and the plates are held together only by the rivet-head, which is objectionable.

In practicing my improved process I first coat the surfaces of one of the plates in a suitable manner or all plates when [illegible]

as a core is in contact with the other plate, [illegible] melting material—such as a mineral paint, oil, or an oxide, or an enamel. Then the rod E is inserted in the hole therein, and the terminals of the electric circuit are brought in contact with the back sides of the plates, preferably at points near and surrounding the ends of the rivet, which latter is inserted from said terminals in any to and manner. By this arrangement the current is passed from one of the terminals or metal blocks holding or pressing the plates together into one of the plates in the vicinity of the rivet from the said plate to and through the rivet to the other plate, and then from the latter plate to the vicinity of and rivet to the other terminal or metal block. The method may be practiced by means of apparatus varied in form and construction and different from that shown in the drawings, although this is suitable for carrying out my method.

In the accompanying drawings, Figure 1 represents an elevation of apparatus for riveting by my method, and Fig. 1 is another form to be employed when pressure is applied to the ends of the rivet. Fig. 3 is a sectional view of the plates and rivet after the operation has been effected. Fig. 4 is a sectional view of the plates after the insulating material has been applied and the holes drilled, but before the plates are placed together and the rivet inserted in position; and Fig. 5 is a section of rivet having insulating material on its ends.

Like letters of reference indicate corresponding parts.

Referring now more particularly to the drawings, A and A' indicate two metal plates to be secured together by means of a rivet B, placed in a hole or holes passing through lapped portions of the plates having insulating material I between them, and D and D' indicate two metal blocks or terminals of a suitable electric circuit out of sufficient size to conduct a current of large volume without heating greatly heated thereby.

The heating-current employed may be the kind from any suitable source—as by the use of the dynamo in my prior patent, No. 469,211, dated April 26, 1892. The current is conveyed by means of cables of good conductivity C and C' to the blocks D and D', which are insulated one from the other as shown at E, to prevent the current short-circuiting around the rivet. The metal block D is in the shape of a plunger supported by the end of the upper arm of the frame G and may be raised and lowered upon the work as found necessary by means of the screw H. The block D' is stationary, forming an anvil, is connected with the cable C', and is fixed to the bottom of the lower arm of the frame. The conducting-blocks D and D' are similar to and opposite each other, so that D is movable toward and from block D'. After the plates are placed in position and the rivet inserted the upper block D is forced down by means of the screw H upon said plates to hold or press them together and at the same time make good electrical connection with the rivet. The upper block D is followed up as the rivet is upset with its end of the rivet, and the lower block is also followed up in a similar manner, but for convenience the latter is kept in contact or nearly in contact with same by means of the insulating material I. In Fig. 1 the upper block is shown fitted with insulating material. When the said blocks are in position the current is closed, a full and even amount of the insulating material between the plates and the insulation at the ends of the rivet, the current is passed through the plates and rivet-block, as before mentioned, effecting a thorough union of the sides of the rivet to the plates or metal body surrounding it, gradually closing it as in Fig. 3. When it is desired to upset or head the rivet slightly outwardly, I may be provided to work in the block D', as shown in Fig. 3 of the drawings, by means of a pivoted lever G, coupled at one end to said plunger D, as at D', and at the other end to a link L. By depressing the handle of the lever G the plunger D is lifted and pressure is applied to the end of the rivet to upset or head the rivet or to perfect the union of the parts. The tapping surfaces of said plates may be coated with the insulating material I, but it would have to be cut away or removed to fit the plunger D and the anvil D' to adhere to the purposes of my invention.

It will be obvious that an ordinary electric riveting apparatus may be employed and the current passed through the rivet and plates if heated and with good results, but the insulating material is interposed between the plates. Instead of using a rivet with both ends and placing insulating material on the blocks close to it found to make contact with the ends of said rivet, having the operation, the ends of the rivet-head are heated or covered with suitable insulating pieces or caps, as shown in Fig. 5.

Having described my invention, what I claim as new and desire to secure by Letters Patent, is—

1. The herein-described method or process of electric riveting, consisting in interposing insulating material between the plates or plates to be riveted together, then inserting the rivet into the rivet-hole or holes, and passing a heating electric current through the rivet and plate in order to the ends of the rivet to the metal body through which it passes.

2. The herein-described method or process of electric riveting, consisting in interposing insulating material between the plates or plates to be riveted together, then inserting the rivet into the rivet-hole or holes, then passing a heating electric current into one of the plates in the vicinity of the rivet-hole, and said plate to and through the rivet to the

other plate, and then from the latter plate in the vicinity of said rivet to unite the sides of the same to the metal body through which it passes.

3. The herein-described method of electric riveting, consisting in interposing insulating material between the plates, pressing the same together and heating the rivet inserted through the plates by a heavy electric current flowing through the rivet and plates to unite the sides of the rivet to the metal body through which it passes.

4. The herein-described method of electric riveting, consisting in interposing insulating material between the plates, pressing the same together, and heating the rivet inserted through the plates by a heavy electric current flowing through the rivet and plates to unite the sides of the rivet to the metal body through which it passes, and then applying pressure to perfect the union, as desired.

5. The herein-described method of electric riveting, consisting in interposing insulating material between the plates, pressing the same together, heating the rivet inserted through the plates by a heavy electric current flowing through the rivet and plates to unite the sides of the rivet to the metal body through which it passes, and then applying end pressure to the rivet to perfect the union of said parts.

6. The herein-described method or process of riveting, consisting in interposing insulating material between the plates and heating the rivet and plates electrically while in position to weld or unite the sides of the rivet to the metal body through which it passes.

7. The herein-described method or process of riveting, consisting in interposing insulating material between the pieces or plates to be riveted together, then inserting the rivet into the rivet hole or holes, insulating the ends of the rivet, then passing a heating electric current into one of the plates in the vicinity of the rivet from the said plate to and through the rivet to the other plate, and then from the latter plate in the vicinity of said rivet, to unite the sides of the same to the metal body through which it passes.

8. The herein-described method or process of riveting, consisting in interposing insulating material between the pieces or plates to be riveted together, then inserting the rivet into the rivet hole or holes, holding the plates together by applying metal blocks on each side, insulating the ends of the rivet from the blocks, then passing a heating electric current into one of the plates in the vicinity of the rivet from the said plate to and through the rivet to the other plate, and then from the latter plate in the vicinity of said rivet, to unite the sides of the same to the metal body through which it passes.

9. The herein-described method or process of riveting, consisting in interposing insulating material between the pieces or plates to be riveted together, then inserting the rivet into the rivet hole or holes, holding the plates together by applying metal blocks on each side, insulating the ends of the rivet from the blocks, then passing a heating electric current into one of the plates in the vicinity of the rivet from the said plate to and through the rivet to the other plate, and then from the latter plate in the vicinity of said rivet, to unite the sides of the same to the metal body through which it passes, and then applying pressure to perfect the union, as desired.

10. The herein-described method or process of riveting, consisting in interposing insulating material between the pieces or plates to be riveted together, then inserting the rivet into the rivet hole or holes, and then passing a heating electric current through and between the plates and rivets, to unite the sides of the same to the metal body through which it passes.

In testimony whereof I have hereunto signed my name this 22d day of April, 1890.

UNITED STATES PATENT OFFICE.

CHARLES L. COFFIN, OF DETROIT, MICHIGAN.

PROCESS OF ELECTRICALLY WELDING METALS.

SPECIFICATION forming part of Letters Patent No. 437,571, dated September 30, 1890.

Application filed April 8, 1890. Serial No. 347,115. (No model.)

To all whom it may concern:

Be it known that I, CHARLES L. COFFIN, of Detroit, in the county of Wayne and State of Michigan, have invented a new and useful Improvement in Process of Electric Welding and Metal-Working, of which the following is a specification.

My invention consists of an improved process of electric welding and metal-working, hereinafter fully described and claimed.

The drawings represent apparatus by which my invention may be practiced. Figures 1, 2, and 3 are perspectives, and Figs. 4 and 5 are partial elevations.

In Fig. 1, T represents a table, upon which are mounted two posts A and A', the upper part of post A' being made movable and controlled by a screw-shaft E, having a crank F. I represents insulation in all the figures. C C represent clamps supported on posts A and A', but insulated therefrom, the upper half of each clamp being movable by means of a winch G and sliding block H or in any other convenient manner. B represents a post, movably mounted on table T, carrying an anvil-block D, preferably of carbon, which is movable vertically by a screw-shaft L. B' represents a post secured to but insulated from table T, which carries a vertically-sliding head K, at the lower end of which is a conductor D', (preferably of carbon.) The post B' is connected by the conductor Y with one pole only of a generator, and the clamps C C are connected by a branched conductor Y', in which there may be resistance-switches S to equalize the resistance of the branches with the other pole of said generator. M M represent the articles to be welded together, which are clamped in the clamps C, and are supported by the anvil D, either in contact, as shown in Figs. 1, 3, and 5, or separated, as shown in Fig. 4.

In the operation of this apparatus, the articles being clamped, as shown in the figures, the conductor D' is brought down to make contact with the articles M M, and a heating-current is then passed through the conductors Y Y', traversing the articles M M and passing out through conductor D', or vice versa, by which the articles M M are heated at their point of contact with the conductor D', when they may be pressed together by the winch E F to form the weld, which may be completed by hammering, rolling, &c.

In Fig. 2 conductor D' and anvil D are both represented by one pair of tongs, which are clamped on the article M at the point where it is desired to heat said article, and the clamps C C are connected with the article M at each side of this point, being both connected by a branched conductor Y' with one pole of a generator, and the tongs D' being connected by the conductor Y with the other pole of said generator.

In Fig. 4 the arrangement is substantially the same as Fig. 1, the conductor D' being raised and lowered by an eccentric K, and a similar eccentric being substituted for the shaft L to lower and raise the anvil D''. In this figure the articles M M pass through hollow magnets N N and are not in contact, one being connected by the conductor Y with one pole only of a generator, and the conductor D' being connected by the conductor Y' with the other pole of the generator, one of the articles M being directly heated by the current and the other heated by radiation.

In Fig. 3 the apparatus of Fig. 4 is shown as applied to welding a hoop, which is held in the upper clamp C', provided with the eccentric K', and the clamps C C, which are connected with the branched conductor Y', are in this case connected with the hoop on opposite sides of the joint.

In Fig. 5 the mechanism of Figs. 3 and 4 is indicated as applied to making a lap-joint between the articles M M.

A description of the operation of Fig. 1 applies to all the figures.

What I claim as my invention, and desire to secure by Letters Patent, is—

The process herein described of welding metals electrically, which consists in bringing the parts to be welded in contact with an anvil, and a conductor, which is connected with one pole of a generator, connecting said articles with the other pole of said generator only, passing a heating-current through the articles and conductor, and pressing the articles together and forming the weld while in contact with said conductor, substantially as set forth.

UNITED STATES PATENT OFFICE.

ELIHU THOMSON, OF SWAMPSCOTT, MASSACHUSETTS, ASSIGNOR TO THE THOMSON ELECTRIC WELDING COMPANY, OF MAINE.

METHOD OF ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 444,928, dated January 20, 1891.

Application filed June 14, 1890. Serial No. 355,502. (No model.)

To all whom it may concern:

Be it known that I, ELIHU THOMSON, a citizen of the United States, and a resident of Swampscott, in the county of Essex and State of Massachusetts, have invented a certain new and useful Method of Electric Welding, of which the following is a specification.

My invention relates to a process of electric welding in which the surfaces to be welded are pressed together to from a union, and the heating of the surfaces to the desired plasticity is effected by means of an electric current passed across the joint or line of proposed union.

My present invention relates more particularly to the process of joining or welding together strips, sheets, plates, or bars of metal where it is desirable to form a joint of considerable length, and is especially applicable to the welding of plates together at their edges, instead of riveting, to the welding of ribs or strips of metals to plates for the purpose of strengthening the same, to the formation of pipes by welding a longitudinal joint, to the welding of half-round or other shaped strips on one or both sides of a plate or strip of metal, and to other similar classes of work, as will be obvious.

My present invention consists, essentially, of forming an elongated joint by the electric welding process by feeding the work in the longitudinal direction of the joint through suitable pressure devices, the work being properly arranged, so that the pressure devices will press the surfaces to be welded together and simultaneously passing an electric current through the work at the point of pressure.

In carrying out my invention I prefer to use as the pressure devices suitable rolls or segments of rolls which are included in the heating electric circuit and from which the current passes to the work and across the surfaces pressed against one another by such rolls. In combination with the rollers or similar devices I employ any usual or proper means, such as screws, levers, or other devices for forcing them toward one another. As the work is passed through such rolls with a continuous motion, each point as it comes between the rolls is heated and the surfaces pressed together by the pressure applied in a line transverse to the plane of the surfaces to be welded.

In the accompanying drawings I have illustrated, in Figures 1, 2, and 3, various forms of apparatus suitable for carrying out my invention. Fig. 4 is an edge view of two rolls of special form that may be used in carrying out my invention. Fig. 5 illustrates rolls or pressure devices of a special construction invented by me and hereinafter claimed.

Referring to Fig. 1, R R' indicate two rolls, of conducting material, which are mounted in suitable frames F F', and are supported upon but insulated from a bed-plate D. The frames F F', being of conducting material, may be connected with any suitable source of electric current of large volume through cables C C', or by other means, so that an electric current may be caused to pass from one roll to the other, and through any pieces of conducting material held between them in pressure-contact. The frame F' may be made to slide in the bed-plate D and may be forced toward the opposite roll by means of the screw S, so that the desired pressure may be applied. In this figure I have illustrated the application of my invention to the welding of the edges of two plates M M' together, the plates being shown in end view as in position between the rolls ready to be fed between them in the longitudinal direction of such plates. The edges are slightly overlapped, as shown, and the plates, being in position between the rolls, may be squeezed together by means of the screw S, thus forming an electric contact between them. The electric current being now turned on as it passes from one roller to the other and across the point of pressure will heat the work to the welding temperature and soften the same slightly, after which the screw may be given a few more turns to effect a solid union. The work, hav

1029

ing been thus started, may now be moved along through or between the rollers, so as to bring successive parts of the joint into position to be pressed and heated at the same time. By this operation the metal will become thoroughly united as it passes through and out from between the rolls. It is obvious that the speed of the operation may be varied by varying the rate of heating and the rapidity at which the work may be fed through the rolls.

In Fig. 2 I have shown segments of rolls R R′ to be employed in special work, as in the joining face to face of two strips or plates M M′, which are of comparatively limited length in the direction of the joint. In this case the work is suppesed to be fed down vertically through the rollers and through the bed-plate. The length of the strips and of the joint between them is in this instance supposed to be of about the same length as the face of the segment, so that the pieces may be drawn or forced through and the whole length united by the time it has passed between the segments. The frames holding the segments or rolls are mounted as before described in connection with Fig. 1, and current may be supplied to them in the manner indicated, as by cables C C′, or in any other desired way. In all cases the work may be fed or passed between the rolls by means of power applied to the rolls or segments, in which case the friction of the rolls on the metal will draw the work through. If desired, power may be applied directly to the metal itself, the latter method being somewhat preferable.

In Fig. 3 an apparatus slightly modified from that of Fig. 1 is illustrated. Here the work is supposed to be fed down vertically through the bed-plate and between the rolls, and the movable frame of the roll R′ is a pivoted frame instead of a sliding frame, as in Fig. 1. The point of pivoting is indicated at P. The pressure-screw S is insulated from the frame F′ by engaging with a piece of insulating material, as indicated, let into the frame.

It is obvious that a large variety of work may be done by this process. Thus, as indicated in Fig. 4, the method may be applied to the formation of joints between pieces arranged to make V-shaped troughs or plates, the two parts being welded together at an angle, as represented, but the pressure being applied, as in the cases before mentioned, in such way as to press the surfaces to be welded into contact. The face of the roller may obviously be of any suitable form conforming to the ultimate shape of the finished article desired, and may then be used to shape or conform a flat strip or strips of metal into different shapes in cross-section simultaneously with the welding operation. In such instances, however, it would be necessary to employ a current of somewhat larger volume in order to heat the whole cross-section of the work that is exposed to the surface of the rollers in addition to the parts at or near the joint.

In Fig. 5 I have illustrated apparatus that may be used in welding a strip or rib M to the surface of a plate or strip M′ that is wider than said rib or is of a different shape therefrom. The roller rest or abutment R′ is made with an insulating face or surface immediately beneath the work or in the line with the smaller piece M, as indicated, but is of conducting material, to one side of such line. The effect of this is to cause the current to take the paths indicated by the arrow, so as to take a path through the surfaces of the strip or plate M′ near the edges of the work or joint, thereby causing proper heating and joining of the strip or rib M at its edges as well as at the inner or flat surface thereof.

What I claim as my invention is—

1. The herein-described method of forming an elongated joint by the electric welding process, consisting in feeding the work in the longitudinal direction of the joint through suitable pressure devices while properly arranged, so that the pressure devices will press the surfaces to be welded against one another, and simultaneously passing an electric current through the work at the point of pressure.

2. The herein-described improvement in forming electrically-welded joints, consisting in lapping the pieces to be welded upon one another, passing the lapped pieces through or between suitable pressure devices, forming the electrodes of an electric heating-circuit, and applying pressure to effect the weld.

3. The herein-described improvement in forming longitudinal seams or joints between strips or pieces of metal, consisting in feeding the strips or pieces through suitable rolls while arranged in proper position to be pressed together by such rolls, and at the same time passing a heating electric current from one roll to another and through the surfaces to be welded, as and for the purpose described.

4. The herein-described improvement in electric welding and shaping of metals, consisting in feeding two or more strips of metal to be welded together through forming or shaping rolls in the longitudinal direction of the joint, pressing the surfaces to be welded together by such rolls, and at the same time passing a current from roll to roll of sufficient volume to heat the strips to plasticity, so as to effect the weld and at the same time shape the metal to the desired form in cross-section.

5. In an electric welding apparatus, an abutment or rest for the work, made of insulating material at its surface immediately beneath the parts to be welded and of conducting material to one side of it, so as to cause a cur-

1050

rent to pass or be delivered through surfaces near the edge of the work, as and for the purpose described.

6. In an electric welding apparatus, a pressure and conducting roll a part of the surface of which is a conductor, while another part is a non-conductor, for the purpose of directing the current through the work under pressure.

GEORGE W. BLANCHARD, OF WATERVILLE, MAINE, ASSIGNOR TO THE ELECTRICAL FORGING COMPANY, OF MAINE.

ELECTRIC HEATING-TOOL.

SPECIFICATION forming part of Letters Patent No. 466,266, dated December 29, 1891.

Application filed April 3, 1891. Serial No. 387,490. (No model.)

To all whom it may concern:

Be it known that I, GEORGE W. BLANCHARD, a citizen of the United States, residing in Waterville, in the county of Kennebec and State of Maine, have invented certain new and useful Improvements in Electric Heaters, of which the following is a specification.

This invention has reference to devices for heating articles such as rivets by means of electricity. The primary object of the invention is to produce a device which may be used for heating rivets at locations where it would be inconvenient or impossible to have a forge, and also to provide a new method of handling rivets, whereby the process of riveting is rendered much quicker and the work more effectually accomplished.

The invention consists, first, in the method of heating rivets while the same are in transit from any location to their final place of deposit; and, second, the invention consists of a device similar to tongs, having means for grasping and subjecting a rivet to a heating-current of electricity.

In the accompanying drawings, Figure 1 represents a device constituting that portion of my invention capable of illustration, and Fig. 2 is a modification thereof.

a a represent the two arms or levers of a pair of tongs, pivoted together at *a'*. These tongs are preferably entirely constructed of strong insulating material, such as fiber. The handles are preferably hollow, as shown in Fig. 2, and the jaws have fitted to their extreme ends blocks or electrodes *b b*, of copper or other good conducting material, the adjacent faces of which are formed with a seat adapted to grasp and hold the body upon which the device is to operate. Binding-posts *b' b'* are provided on or near the electrodes to secure the ends of the electrical conductors *c c*, extending therefrom through the hollow handles of the tongs, as shown in Fig. 2, or directly from the posts *b' b'* to a source of electricity C. The circuit may also include the usual resistance box and switch R for the purpose of varying the current. As hereinbefore mentioned, the device is particularly adapted for heating rivets. The jaws or electrodes *b b* are therefore formed on their adjacent faces with grooves.

In operation the handles of the tongs are grasped by the operator, the jaws opened, and the rivet inserted and clamped between them in the ordinary way of operating tongs. The current is then turned on, and owing to the fact that the rivet is of high-resistance material it soon becomes heated and is ready to become inserted into the hole which is to receive it.

In the ordinary process of riveting heavy work the rivets are usually heated in a forge and carried in ordinary tongs from the forge to the place of deposit or the hole which is to receive it. It is then inserted and headed up. In passing the rivet from the forge to the place of deposit it cools considerably, and therefore requires that it be heated in the first instance too hot, or else it is too cold when it reaches the riveter.

My improved method of riveting consists in heating the rivet while it is being conveyed to its place of deposit. This is done by grasping the rivets in the tongs hereinbefore described, turning on the current, and conveying the tongs with the rivet to the hole which is to receive it and inserting the same into the hole. By this method the heating operation and the transportation of the rivet are simultaneous and the result is that the rivet is delivered to the hole at just the right heat without any loss of time.

It will be observed, of course, that the conductors connected with the tongs are flexible and may be of any desired length. It will, therefore, be convenient to carry the tongs from place to place to carry out the method.

I claim as my invention—

1. An electric heating device consisting of tongs, in combination with two electrodes, one secured to each jaw of the tongs and electric conductors secured to said electrodes.

2. An electric heating device consisting of tongs, having insulated handles and means for connecting electric conductors to its jaws.

3. An electric heating device consisting of tongs having hollow insulated handles, electrodes connected with the jaws of the tongs, and electrical conductors extending through the hollow handles and connected with said electrodes, substantially as described.

In witness whereof I have hereunto signed my name in the presence of two subscribing witnesses.

ELIHU THOMSON, OF LYNN, MASSACHUSETTS, ASSIGNOR TO THE THOMSON ELECTRIC WELDING COMPANY, OF MAINE.

ELECTRIC SOLDERING.

SPECIFICATION forming part of Letters Patent No. 406,019, dated April 25, 1893.

Application filed January 23, 1888. Serial No. 297,161. (No model.)

To all whom it may concern:

Be it known that I, ELIHU THOMSON, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, have invented a certain new and useful Electric Soldering, of which the following is a specification.

My present invention relates to an improved method of producing soldered joints between metal pieces, and is particularly applicable to soldering sheet metal pieces flatwise. When applied to tin plate the tin itself which covers the iron plate is often sufficient for the uniting solder. In other cases solder may be applied.

My invention consists in clamping or pressing the pieces together at the seam or joint, passing an electric current through either or both of the pieces to be joined, and in sufficient volume to melt the solder or uniting metal, cutting off the heating electric current, and maintaining the pressure until the joint is sufficiently cool.

Great difficulties have hitherto been experienced in soldering long seams owing to the fact that the cooling takes place unequally and, at the moment the solder sets, parts of the seam contract and draw so as to break the joint. The pressure which holds the pieces together must be continued and the piece held rigidly during the cooling or setting of the solder. This is easily accomplished in my invention since the cutting off of the current allows the pieces to cool, while the pieces still remain clamped and hold firmly during the setting of the fused metal.

My present invention, like my prior inventions in electric soldering, brazing and welding, involves the use of electric currents of low potential but large volume derived from any suitable source, together with suitable devices whereby the current may be cut off or regulated.

My invention comprises further an improvement in electric soldering consisting essentially in establishing an electric resistance to the passage of the current from the clamp or pressure block back of the joint to the metal or the work to be joined. This may be done either by modifying the surface of the pressure block itself or by modifying the surface on which it bears, or both, or by the interposition of a thin septum, layer or zone of resisting material, or material modified in condition or form so as to oppose a resistance to the passage of an electric current. Some of these means for establishing a resistance are hereinafter more particularly described.

In the accompanying drawings:—Figure 1, shows apparatus that may be used in practicing my invention. Fig. 2, is a view of the work. Figs. 3, 4, 5 and 6, show other forms of joint and of work. Figs. 7, 8, 9, 10, 11, 12 and 13, are sectional, side and face views of clamps having particular kinds of contact faces. Figs. 14, 15, 16 and 17, are face and side views of elongated clamps for use in connection with long joints. Fig. 18, is a plan of mechanism for operating an elongated clamp. Fig. 19, is an end elevation of pressure rollers applied to the work of soldering in accordance with my invention. Fig. 20, is an edge view of a roller. Fig. 21, is an elevation of a gang of clamps and mechanism for operating the same successively and establishing electrical connection with them in accordance with my invention. Fig. 22, is a side elevation of a pair of clamps the frame in which they are mounted being shown in cross section.

In Fig. 1, P, P′, are sheet metal pieces such as tin plate which are overlapped for a joint and pressed together at the overlapped portion by pressure pieces C, C′, one or both of which are movable, as C′, under the influence of a screw S, which, turned by a suitable crank or other device, gives pressure to hold the pieces P, P′, firmly and squarely. The pieces C, C′, may be suitably guided so as to move in a right line toward and from the other, the surfaces bearing on the overlap of the plates P, P′, being made true and square so as to bear evenly thereon. Heavy electric currents are conveyed to the clamp pieces C, C′, by conductors K, K′, or in any suitable way from a source indicated by G. In the case of the pieces P, P′, of tin plate, a union takes place at the overlap when a sufficient strength of current to melt the tin between the surfaces has been passed. The current being then cut off the pieces are allowed to cool in position under pressure until thoroughly joined after

which the pressure is taken off and the plate removed. In other cases suction is applied to the joint when hot. The union is facilitated by a flux, if needed. Slightly oiling the melting surfaces with lard oil or other exercise containing oil will usually suffice when the plates P, P', are to glass.

Fig. 3, shows the plate P, P', fastened and in dotted lines, the portion of the contact clamp-plate C'. The clamping movement to secure by regulating or controlling the current may be such as are described in my prior patents, as, for instance, as in 507,503, or the clamping or pressure devices may be suitably modified, as to the shape of their clamping devices, when found desirable. It is not necessary in every case to pass the current across the joint from one plate to the other. The current might be passed in the general direction of the line or plane of the joint.

Fig. 4, shows that the joint to be made may be a double lap instead of the angle lap as in Figs. 1 and 3. The same application of non-adjustable pressure, passage of adjusting current and cooling under pressure with thumb-nut taken off, may be carried out with such a joint.

Figs. 5, 6 and 7, illustrate the union of two tin plate pieces of a different form. P, is a round plate curved up into form. P', is a ring plate with one edge turned in as indicated. The two are put together as in Fig. 5, the pressure blocks C, C', applied to form the meeting surfaces into close and true contact, and current is put on until the tin on the meeting surfaces melts out entire thus as in Fig. 5. The blocks C, C', may be of iron or other metal, as may those of Figs. 1, 2 and 3, but to concentrate the heat to the pieces P, P', I prefer to make them of steel in iron, or copper, and face them with a facing such as lard oxide, or have their surfaces which are to be applied to the work so will be insulated further on.

The facing of lard oxide, E, E', Fig. 7, of the blocks C, C', Fig. 5, is for the purpose of producing an electrical resistance to the work, or where the current enters the work, which tends to the accumulation of heat (occur with low current strength). The join between the metal pieces P, P' and the blocks C, C' should be good and made by interposing the metal and securing the pieces together by clamping for example. Due to account of the difficulty of this, and of the fact that the section is fragile, I prefer another arrangement as indicated in Figs. 8, 9, 10, 11, 12 and 13. This is simply the covering of the faces of the contact and pressure blocks C, C', with soldering-proof insulating covers E, E', which may be of paper, cardboard, mica or a series of pieces of glass cemented together, as in a surface block will fit the work. The arrangement as shown in Fig. 8, a double lap-joint of previous may be made resting on an angle or rabbeted bearing the surface sufficiently covered with metal points, or projections. In Fig. 11, a portion of the covering is shown as the surface projecting a closely placed series of edges of narrow width. In Fig. 12, the edges are rolled and formed as the corrugations of the grooving being rolled. In the form shown in Figs. 13 and 14, which are suitable only a few mm and a little over of such a thick as C, Fig. 14, a multitude of fine projections to project slightly from the face of the C, or E, and are ground down to a level of numerous projecting points to the plate. In all these cases the continuation of the current from the plates held between the blocks is greatly checked by the fine points of the faces as described, and the resistance to the passage of current at the work is increased which in turn results in further softening of the metal plates where pressed up together between the contacting blocks C, C'.

Figs. 15 and 16, show the grooving of the pieces as E, which are long and narrow and are used to engage a piece of work such as in Figs. 1 and 3. Fig. 16, shows the case with the two grooved ends of pieces having a series of points projecting from the surface.

Fig. 17, shows the block C, of Fig. 15, in edge view.

Fig. 18, shows one of the many forms that may be used for uniting sections of pipe, as of the blocks C, C', upon the ends P, P', which are to be united together to convey something in large amount from one vessel to the other through the work. A, holds P, P', in the left hand and holds P, P', in the right hand and holds P, P', in the left hand and holds P, P', in the right hand and holds P, P', in the left hand and holds P, P', in the right hand and

UNITED STATES PATENT OFFICE.

HERMANN LEMP, OF LYNN, MASSACHUSETTS, ASSIGNOR TO THE THOMSON ELECTRIC WELDING COMPANY, OF MAINE.

METHOD OF PRODUCING LOCALLY-ANNEALED STEEL PLATES.

SPECIFICATION forming part of Letters Patent No. 531,197, dated December 18, 1894.

Application filed August 1, 1894. Serial No. 519,214. (No specimens.)

To all whom it may concern:

Be it known that I, HERMANN LEMP, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, have invented a certain new and useful Method of Producing Locally-Annealed Steel Plates, of which the following is a specification.

My invention relates to a novel method of obtaining hardened plates or other pieces of metal, such as steel, locally softened to admit of cutting, tapping or drilling, and is especially useful in the production of Harveyized armor plates which require to be provided with bolt holes, countersinks, embrasures or other holes or openings when in place upon the ship, though it is also applicable to other plates or pieces of metal and whether hardened all through, or merely at and near the surface.

My invention consists essentially in hardening the whole piece of steel or other metal, then locally heating the spot or portion in the body thereof to be softened, to the proper temperature, by an electric current passed through the metal itself, and then allowing the said portion to cool while keeping it supplied with a gradually diminishing amount of heat from such current, the rate of diminution being adjusted, as hereinafter described, to the capacity of the surrounding mass of metal to carry the heat away, so as to cause it to cool gradually and at a sufficiently slow or proper rate to become soft at such heated portion. By producing the local heating through generation of heat in the desired portion of metal itself by the passage of an electric current through such portion, the heating may be much more closely confined or localized and the rate of cooling better controlled.

My invention consists further in certain appliances designed to aid in the purpose of locally heating by the electric current and of confining the heating to the desired spot.

It is well known that an ordinary piece of steel such as tool steel, manganese steel, &c., which, through its peculiar chemical composition has been tempered or hardened by plunging it in water after heating or by otherwise cooling it off rapidly, may be softened again by bringing it to the right temperature and leaving it in the open air to cool off gradually. It may of course be made softer yet by decreasing the rate of cooling by surrounding the metal with some refractory or heat insulating substance such as ashes, magnesia, &c.; but for all practical purposes an ordinary piece of steel may be annealed or softened by allowing it to cool in the air. If, however, the attempt be made to soften or draw the temper at an individual spot in a large plate or piece of hardened metal by heating it to the right temperature and then removing the heating influence suddenly, the surrounding metal will carry the heat away so fast as to chill the heated portion and harden the same as if the heated spot alone had been plunged into water or other cooling medium. Moreover, no covering with any heat insulating material would prevent this inasmuch as a large percentage of the hot metal is in direct contact with cold metal from which it cannot be isolated by any known means. For this reason in the production of Harveyized plates for armor plates, for instance, it has not been found practical to first subject the whole plate to the hardening process and then locally heat the part which is to be cut, tapped or drilled; nor has it been found practical to first cut, tap or drill the metal plate and subsequently harden it, for in the hardening operation the plate is liable to become deformed or to crack around the openings or holes. It has, therefore, been found necessary either to tap, cut or drill the hardened metal at great difficulty and expense or else to locally apply some material to parts of the plate which will prevent it from becoming hardened during the hardening process.

My invention obviates the difficulties and objections heretofore met with in dealing with hardened armor plate having a skin or coating of hardened metal as well as in dealing with other large masses or pieces of hardened metal which require to be cut or formed at some part, and consists essentially in first producing a complete plate or piece of the hardened material including the portion to be cut

1062

or formed, then by the passage of an electric current through the metal, heating the portion to be formed or cut to the proper temperature for drawing the temper and then allowing it to cool at such portion while supplying it with a gradually diminishing amount of heat from such current to prevent the fall of temperature in the heated portion due to the presence of the large masses of metal in direct contact with it from being a too rapid one.

By my invention the hard steel plate may be softened in isolated spots so that it may be readily drilled and tapped at such isolated spots alone, or continuous lines or extended surfaces may be softened for the purpose of allowing the material to be cut along the softened line.

In carrying out my process by the use of electric currents a transformer having a secondary adapted to supply current of large volume, such as is employed in electric metal working operations, may be used and the terminals thereof brought into contact with the previously hardened plate or mass of metal on either side of the spot to be annealed or softened. The current is made to enter the plate at one contact and leave it at the other bringing the intermediate portion to a dull red heat. If the process were stopped at this point and the current withdrawn, the metal would chill and be as hard in the spot as anywhere else but, if instead of withdrawing the current suddenly it be gradually diminished in amount in any well known manner as for instance by proper regulating devices, the temperature of the heated portion may be made to fall as gradually as it would if that portion were separate from the whole piece and left to cool on its own account. The depth to which this local softening process can be carried depends largely upon the arrangement of the contacts or manner of introducing the electric current by which the heat is generated in the body of the metal by the passage of the current through it. If the plate or piece of metal be hard through its whole thickness and not merely on its skin surface, the current may be made to enter at one side and leave at the other passing entirely through the mass of metal. On the other hand if only the skin is to be treated the contacts may be placed side by side upon the same surface.

The diminution in the rate of flow of the current after the metal has been brought to the proper heat may be produced by any desired form of current regulator as, for instance, by means of a reactive coil in series with the heating apparatus or by a resistance in series with the field of the generator furnishing the alternating currents for the heating transformer. Preferably, an automatically operating regulator actuated by gravity or other power is employed. The action of such regulator is adjusted to the desired rate by clockwork or any other time adjusting means which shall produce the required rate of decrease of such heating current in the metal.

The amount of heat furnished by the current might be gradually diminished or removed by moving the electrodes along the surface of the metal at the parts where it is to be locally heated and this may be a desirable way of producing a softened line of material in the hardened mass the rate of movement being, of course, adjusted to the particular circumstances of each case and being made slower where the mass of surrounding cold metal is larger or heavier. I have found, however, that good results may be obtained by adjusting the action of a current regulating resistance applied to any proper portion of the electric apparatus which furnishes the heating current in such manner as by its action to cause a diminution in the flow of said current.

In order to prevent the current from spreading too much and heating the metal beyond the desired zone of softening care should be taken not to use too heavy or powerful an electric current. This is particularly the case where the attempt is made to pass the current through the metal from one side of the plate to the opposite side.

I have obtained good results in the case of Harveyized plates by means of two copper contacts resting side by side upon the plate about one inch apart and each copper contact being about one inch square, then passing the current through the metal until the temperature between the contacts show a just visible red, and then reducing the heating current very gradually through a period of about ten minutes in which period the metal is allowed to cool gradually past the critical stage or temperature at which the material proceeds to set or become hard if the change of temperature is at such point rapid or sudden.

In the accompanying drawings I have shown some of the electrical apparatus that may be employed in practicing my invention.

Figure 1, is a general side elevation of an apparatus in which a transformer is used for heating one side of a piece of metal at an isolated spot. Fig. 2, is an edge elevation of the transformer. Fig. 3, shows in end elevation the transformer electrodes or contacts. Fig. 4, illustrates the manner of applying the electric contacts when the current is to be passed through from one side to the opposite side of the plate. Fig. 5, shows on a larger scale a vertical transverse section through the carriage K, taken in the plane of the axis of roll. Fig. 6, is a vertical section taken longitudinally of the carriage in the planes indicated by the line 7, 7, of Fig. 5; and Fig. 7, is a vertical section through the electrodes B, B, taken in the plane of the axes of pipes C, C, and a.

Referring to Fig. 1, A, indicates the transformer which may be of any usual type suitable for generating heavy currents.

S, is the secondary and B, B, the contacts reduced toward their lower ends to produce the small contact surfaces *b*, *b*, and made, preferably, adjustable on the terminals of the secondary for the purpose of varying the extent, of heated metal between them. These contacts or electrodes are preferably hollow and a stream of cooling liquid is circulated through them by means of pipes C, C.

At *c*, is a pipe connecting the two hollow electrodes.

One way of mounting and constructing the electrodes B, B, is illustrated in Figs. 1, 2 and 7. Each electrode is seated in a slide formed between projections on the lower end of the secondary S, and has a bolt *a*, passing through it and through slots in said projections as shown. On the ends of these bolts are washers and nuts for clamping the electrodes at the desired distance apart. The pipe *c*, is preferably of insulating material and may be firmly attached at one end in the wall of one electrode while it slides through a gland in the wall of the other electrode, or it may be of metal and be insulated from the electrodes by suitable bushings of insulation. The water pipes C, may be rigidly secured in the electrodes and move bodily therewith or they may pass through glands in the walls of the electrodes as desired. I have shown them as rigidly attached to the electrodes and, on account of their considerable length, depend upon their resilience in the adjustment of the electrodes. By thus keeping the contacts artificially cool the heating in the mass of metal is better localized at the portions thereof between the electrodes themselves. In practice it will be found that when only slight contact pressure is used there is a tendency of the metal at the surface in contact with said electrodes to heat more than at the portion between them but by artificially cooling the electrodes the heating may be better confined as stated.

The flexible conductors which supply the primary of the transformer are indicated at D, D. In their circuit is shown a reactive coil E, of any suitable construction whose core F, is suspended from an adjustable dash-pot G, of any suitable character employed for the purpose of checking the descent of the core by gravity into the reactive coils. By this device a retarded rate of action of the regulator is obtained to produce the diminished rate of flow of the current. To suit different cases, an adjustment may be provided to regulate the rate of descent or movement of the movable portion of the regulator consisting, in this case, of the movable core F. When a dash-pot is employed the adjustment may be obtained by providing the dash-pot with a by-pass having a cock G', which will regulate the rapidity of the flow of air or liquid in the dash-pot from one side of its piston to the other. By adjusting this cock the flow of current may be caused to diminish at the desired rate varying as will be understood under different circumstances.

H, indicates a Harveyized plate under treatment for local softening and the portion involved in the heating current is indicated by the shaded portion between the electrodes. To aid in moving the transformer over the surface of the metal plate H, it may be hung from a rod I, by a ball and socket joint or other flexible suspension. The rod I, is in turn mounted on a carriage K, which has wheels L, running on the rails M, of a swinging crane or bracket N. Wheels P and R, operate on suitable mechanism mounted on the carriage and connected with the rod I, and the wheels L, to lower the transformer or to move it along the rails. Various forms of mechanism may be devised for manipulating the transformer and its carriage. For the purpose of illustration I have shown the carriage provided with a recess for the reception of a steel nut T, through which and suitable ways in the carriage passes the screw U, which is rotated by wheel R, in moving the carriage and the suspended transformer over the plate. As a means for raising and lowering the transformer, I have shown a worm nut as V, located in the frame of the carriage and turned about the suspending rod I, by means of the worm W, which is rotated by the hand wheel P. By these means and by the swinging crane the transformer may be adjusted over any desired spot on the plate or mass of metal H.

As will be seen in Figs. 3 and 4, the electrodes or contacts where they engage with the mass of metal are made rather small, this being for the purpose of localizing the heating current so far as possible and the undue heating at such points is prevented by the artificial cooling.

What I claim as my invention is—

1. The herein described method of obtaining a hardened piece of metal with a portion only in the body thereof softened, consisting in hardening the whole piece, generating heat in the portion to be softened by an electric current passing through the metal itself at the portion whose temper is to be drawn, and then gradually diminishing the amount of heat supplied by the current to said heated portion at such a rate that, at any period of time, the amount of heat supplied is nearly but not quite equal to the amount of heat being absorbed by the surrounding metal, as and for the purpose set forth.

2. The herein described process of locally softening or drawing the temper from a Harveyized plate or similar plate having a skin of hardened metal, consisting in passing a heating electric current through the metal from one point on the surface thereof to another point by electric contacts engaged with said surface, heating the metal by the heat generated through the passage of the current in the metal, and to a dull red heat, and then

1064

gradually removing or withdrawing the electric current, at such rate that the amount of heat supplied is nearly but not quite equal to the amount of heat being absorbed by the surrounding metal, as and for the purpose described.

3. In a heating device employing a transformer, the combination with the secondary, of hollow contacts or electrodes connected thereto, feeding and discharge pipes connected respectively to said electrodes, and a pipe of insulating material connecting said electrodes for the purpose set forth.

4. In a heating device employing a transformer, the combination with the secondary, of hollow electrodes seated in ways in the ends of the secondary and adjustably secured in place, feeding and discharge pipes connected respectively to said electrodes, and a connecting pipe between the electrodes properly insulated therefrom and having a sliding union with one of them.

5. In an apparatus for producing local annealing, the combination with the heating device, of a swinging bracket provided with a track, a carriage running on said track for carrying said heating device, a screw located in said bracket, a nut in the carriage fitted to said screw, a hand wheel for turning the screw to propel the carriage, and means for raising and lowering said device for the purpose set forth.

6. In an apparatus for producing local annealing, the combination with the heating device, of an overhead track, a carriage on said track, a screw-threaded rod connected to the heating device, a worm-nut located on said carriage to receive said rod, a worm for operating said nut to thereby raise and lower the heating device, and means for moving the carriage along its track for the purpose set forth.

7. The combination, substantially as described, with an electric heating apparatus, of an automatic current regulator for producing a diminished rate of flow of the heating current, and a retarding device connected with said current regulator whereby a slow diminution in the supply of heat may be produced.

UNITED STATES PATENT OFFICE.

HERMANN LEMP, OF LYNN, MASSACHUSETTS, ASSIGNOR TO THE THOMSON ELECTRIC WELDING COMPANY, OF MAINE.

APPARATUS FOR ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 553,923, dated February 4, 1896.

Application filed June 17, 1891. Serial No. 396,547. (No model.)

To all whom it may concern:

Be it known that I, HERMANN LEMP, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, have invented certain new and useful Improvements in Apparatus for Electric Welding, of which the following is a specification.

My invention relates to those electric metal-working operations in which one or more pieces of metal are heated by means of the electric current.

The object of my invention is to provide for a more thorough and uniform heating of the work in the operation; and the invention consists in applying to the metal heating electric currents of different frequency during the manipulation thereof, and the invention consists in the combination, arrangement and operation of parts as hereinafter fully described and set forth in the claim.

My invention is especially applicable to a metal-working operation consisting in the forming of long joints between strips, plates, bars or rods—such as boiler-plates or other articles which are at present riveted—by a welding, soldering, cementing or similar operation, though it is likewise applicable to the simple shaping, rolling or forming of a metal rod, bar or strip fed between the forming pressure devices.

I shall hereinafter describe my invention more particularly as applied to the formation of joints between long strips, bars or plates.

In carrying out my invention the heating-currents applied to the work may be two independent currents passed through the strips to be joined one in a direction parallel to the joint and one transversely or at right angles to the joint, or nearly so. Such transverse current might be one made to pass through or across the pieces diagonally, as the result of two independent alternating currents interfering or displaced in phase.

I include in my invention by the term "transversely" a current passed diagonally as well as at right angles through the metal piece. The two heating-currents may be passed through the same portion of the one or more strips, plates or rods at the same time or they may be entirely distinct and sent through one after the other. The heating-currents might be passed through a portion of the work longitudinally, which is some distance removed from the pressure devices and the current passed through such portion transversely only after it has reached the pressure devices.

In carrying out my invention I prefer to employ two distinct sources of energy supplying current to the work.

In the accompanying drawings, Figure 1 illustrates in plan an apparatus that might be used for the purpose of uniting plates, strips, or bars of metal and heating the same in the manner employed previous to my invention. Fig. 2 is an end view of the same. Fig. 3 illustrates an apparatus that may be employed in practicing my present invention. Figs. 4 and 5 illustrate other apparatus, also suitable for the purpose of my invention. Figs. 6 and 7 are graphic representations of currents as used in the method hereinafter explained.

Referring to Fig. 1, B and B′ indicate the secondaries of two transformers, each secondary being made in the manner commonly employed in electric metal-working apparatus, as a solid bar or mass of copper having a primary C or C′ applied in a groove in its side. A A′ are the laminated iron cores for said transformers.

D D′ D^2 D^3 are electrodes or contacts which are designed to pass heating-currents from the transformers into the work, here indicated at M as consisting of two strips of metal fed in the direction of the arrow between the electrodes or contacts. The electrodes or contacts D′ D^2 are in the form of rollers and constitute pressure devices that will serve to unite the metal or otherwise operate upon it as its heated portions pass between them. The two electrodes D D^3 may be similarly constructed as rollers and one of them provided with a screw for pressing it firmly against the work.

In using this apparatus, according to the old method, the heating-current was caused to pass through the section of metal included between the electrodes in the direction of the arrow from the point where the contacts D D^2 bear to the point where the pressure devices D′ D^2 bear, or to some point between

the pressure devices and the first-named contacts or rollers—that is to say, the current was passed in a longitudinal direction through the work before it reached the point where the pressure devices were applied. When the current is applied in this way, the work being drawn in the direction indicated by the arrows, the rollers D D^2 being forced toward each other slightly would effect the welding or otherwise act upon the heated metal. In this operation the work has been found to heat principally between the extremities of the secondaries or at the intermediate portion lying between the two sets of electrodes or contacts; but the parts of the work near the rollers would keep comparatively cool, because of the fact that the rollers being of large mass and good conducting material would have a considerable cooling effect. Hence it frequently happened that by the time the heated work reached the point of application of the pressure devices it would be cooled down so that the rollers could not act with the best effect.

It has also been proposed in some cases to pass the current transversely through the work—that is to say, from contact D to D^2, or reversely, and also from roller D′ to D^1, or reversely. This would be effected by properly combining the transformers as to polarity so that they should work in series with one another. In this method the work would heat at or near the contacts or electrodes; but the action was not satisfactory, because the part which would be heated between D and D^2 would cool while passing to the pressure devices and would have to be reheated at the latter point in order that it might be welded or formed. Such a process would obviously be a wasteful one.

My invention avoids the difficulties incident to the methods just explained and produces a uniform, effective and economical heating of the work.

In Fig. 3 I have illustrated apparatus which may be used for the purpose of carrying out my invention. I have shown the secondaries of transformers as the source of the heating-current, but do not limit myself to the employment of such instrumentalities.

In Fig. 3 I have shown practically two sets of transformers, one consisting of secondaries B B′, primaries C C′, and cores A A′, the other consisting of secondaries B^2 B^3, primaries C^2 C^3, and cores A^2 A^3. The two secondaries B B^2 on one side and B′ B^3 on the other are united in a single casting, but practically form each a separate secondary circuit. The contact-terminals of said secondaries are indicated at D D′ D^2 D^3 D^4 D^5. The terminal D′ serves as a common terminal for the two transformer secondaries B B^2, and the terminal D^3 serves as a common terminal for the transformer secondaries B′ B^3. Those terminals which are not employed for applying the pressure may be, as indicated, simple brushes, while those—to wit, D^4 D^5—which are used for applying the welding or forming pressure are rollers. By connecting the primaries A and A′ to the source of energy in a manner to cause both poles or contacts D D^2 in the respective secondaries to be of one sign and both poles or contacts D′ D^3 thereof to be of the opposite sign a current will flow in the work between the point of application of contacts D D^2 and the point of application of contacts D′ D^3, the secondaries then supplying the current in multiple, and that portion of the work extending from D D^2 to D′ D^3 serving to complete the circuit in the respective secondaries. By connecting the primaries C^2 C^3 to the source of energy in a manner to cause the poles or contacts D′ D^3 of the respective secondaries to be of unlike sign and the poles or contacts D^4 D^5 thereof to be of the reverse unlike signs respectively the current will pass transversely through the strips, bars or rods constituting the work at the points of application of the contacts D′, D^3, D^4 and D^5—that is to say, current will flow through the secondaries in series including the portions of work between D′ and D^3 and between D^4 and D^5. As the work is supposed to be continually moving along, any particular section will be first heated by the current passing longitudinally and then by the current passing transversely through it.

Fig. 4 illustrates practically the same arrangement, with the exception that the two sets of transformers are entirely separate as to their secondaries, and an extra pair of contacts is therefore required. The arrows indicate the directions of the current in the two systems.

Fig. 6 graphically shows the necessary conditions of the current that two secondaries may be in series and heat the work transversely, as in the second heating described in connection with Figs. 3 and 4. The full-lined curve may represent the waves of the alternating current in the secondary B^2, Fig. 4, and the dotted curve the waves of current in secondary B^3. It will be seen that when the current in B^2 is at a maximum and of positive sign, say, that in B^3 is at zero, but approaching its maximum negative sign, so that the two currents are in series, and the flow of currents as before mentioned. In order that the two currents may be in multiple, as in the longitudinal heating, the phases of current in each secondary must rise and fall simultaneously, or, in other words, coincide.

Fig. 5 illustrates apparatus wherein one secondary is made to provide the two heating effects. Each secondary is provided with two primary coils. B has the coils C and C^2, and B′ the coils C′ and C^3. C and C′ are connected in such manner that the secondary currents will be in multiple, and C^2 C^3 in such manner that the secondary currents will be in series. Each "set" of primaries is supplied from different sources of electric energy, one source being an alternating current having a greater frequency than the other. For instance, C C

is supplied with current from machine E and C^2 C^3 from machine E'. Suppose the current from E' has a frequency that is greater than that of E, then the currents may be graphically shown as in Fig. 7. The dotted curve is the current E' and the full curve that of E. It will be noticed that at certain points, as at Y, the two curves coincide, and the secondaries B B' will supply current to the work in multiple. At some other instant the curves will be just opposed to each other and the currents of B B' will be in series. At intermediate points a combination of effects will be produced, which may be readily studied out from Fig. 7.

The arrows in Fig. 5 denote the direction of movement of the work.

It will be obvious that, as in the case of Figs. 3 and 4, the pressure-rolls, Fig. 5, might be made the terminals of the heating source, so that the current passed transversely through the work would pass at the point of application of the pressure. It is also apparent that as the primaries furnishing longitudinal current are independent of those furnishing the transverse current, regulating devices may be used in each circuit to cause one or the other heating effect to predominate. In Fig. 3, R and R' are such regulating devices, so that if it is desired to weld stock of large section a heavier longitudinal current may be used without increasing the transverse current. Thus, for instance, the longitudinal current would be increased when the thickness of the piece to be welded was increased, but where the width was not. This would make a heavier path for the longitudinal current, but the section of stock through which the transverse current flowed would be no greater. The length of the path through the work for the transverse current might be slightly increased but would be almost nothing as compared with the increased section for the longitudinal current; or, if the increase of thickness were attended by an increase of width then the transverse current would be increased in the proper ratio. Again if the width of the stock was increased and the thickness correspondingly decreased in such ratio as to maintain the same area of cross-section transversely through the bar or bars to be heated the longitudinal current would remain the same while the transverse current would need to be larger, as the cross-sectional area of the path would now be larger.

What I claim as my invention is—

In an electric metal-working apparatus, the combination substantially as described with two transformers supplying heating-currents to the same work, of alternating-current sources connected respectively to the primaries of said transformers, and adapted to supply alternating currents of different frequency.

UNITED STATES PATENT OFFICE.

WILLIAM ROBINSON, OF BOSTON, MASSACHUSETTS.

RAIL-JOINT.

SPECIFICATION forming part of Letters Patent No. 574,942, dated January 12, 1897.

Application filed November 14, 1894. Serial No. 528,715. (No model.)

To all whom it may concern:

Be it known that I, WILLIAM ROBINSON, a citizen of the United States, residing at Boston, in the county of Suffolk and State of Massachusetts, have invented a new and useful Improvement in Rail-Joints, of which the following is a specification.

This invention relates to improvements in the rail-joint shown and described in my application for a patent thereon filed October 7, 1893, Serial No. 487,530, and I do not therefore herein claim anything described and broadly claimed in the aforesaid application.

The nature of my invention will be understood from the description which follows, reference being had to the accompanying drawings, which form a part of this specification, in which—

Figure 1 is a top view of a girder-plate, illustrating a part of my invention. Fig. 2 is a side view of the same; and Fig. 3, a cross-section through the lines $x x$, Figs. 1 and 2. Fig. 4 shows the end of a rail with the girder-plate secured thereto; and Fig. 5 is a cross-section through the line $y y$, Fig. 4. Fig. 6 is a duplication of Fig. 4 on the opposite end of the rail, or preferably for my purpose, as shown, on the end of the rail adjacent and corresponding to that shown in Fig. 4. Fig. 7 is a cross-section through the line $z z$, Fig. 6. Fig. 8 shows Figs. 4 and 6 combined and the invention thus more fully developed. Fig. 9 is a cross-section through the line $x' x'$, Fig. 8. Fig. 10 is a horizontal section through $y' y'$, Fig. 8. Fig. 11 shows the side splice-bar, and Fig. 12 a cross-section of the same. Fig. 13 shows the side splice-bar secured to the end of a rail, and Fig. 14 is a cross-section of the same. Fig. 15 shows a similar side splice-bar for the adjacent rail, and Fig. 16 a cross-section of the same. Fig. 17 shows said splice-bar and rail secured together, and Fig. 18 a cross-section of the same. Fig. 19 shows the rail-joint complete in elevation, and Fig. 20 is a cross-section of the same.

A is a railroad-rail, to the bottom of which the girder-plate B is rigidly secured, preferably by the electric welding process. The girder B, as shown in the drawings, has one half of its length projecting under and welded to the bottom of the rail A, the other half projecting beyond the end of said rail and under the adjacent rail for the purpose of supporting the latter.

The form of the girder-plate B is peculiar. By referring to Fig. 10 and some other figures it will be seen that the vertical web of the plate B is provided with inwardly-projecting vertical ribs or lugs b, while the corresponding plate B' is similarly provided with inwardly-projecting ribs or lugs b'. The dotted line passing longitudinally midway between the plates B B' coincides with the center line of the rail, as shown also in dotted lines in Figs. 5, 7, and 20.

The reason for making the girder-plate B in the form described is this: When two pieces of metal are electrically welded together, the molten metal flows so as to make a rough and enlarged joint, and when one piece of metal is thus welded to another in such a way as to form an angle between the two the angle is partly filled up and rounded out by the molten metal. If, therefore, the plates B B' were formed with a continuous smooth edge on their inner surface and were welded with this edge coinciding with the longitudinal center line of the rails, the molten metal would partly fill up the angle formed between the plates and the rails at the longitudinal center line of the latter. As a consequence the aforesaid plates B B' could not come close together because of the intervening overflowed metal, that is, the adjacent rails would be out of alinement. In the present instance, however, the girder-plates B and B' are located to one side of the center line of the rails, leaving a considerable open space between the main body or vertical webs of said plates. At the same time the projecting ribs b b' extend under and even beyond the center line of said rails, whereby the adjacent rails are centrally supported by each of the plates B B'.

It will be observed that the ribs b b' alternate with each other, but do not come close together; also, that there is space left between said ribs, respectively, and the webs of their opposite girder-plates. Thus the overflow of molten metal taking place in welding the plate B to the rail A will not interfere with the proper location and alinement of the plate B' when the adjacent rails are brought together, nor, on the other hand, will the over-

flow metal caused by welding the plate B' to the rail A' interfere with the proper position and alinement of the plate B under similar circumstances, since there is sufficient space left between said plates B B' to allow for the overflow metal without the latter interfering with the proper position of adjacent parts. The plates B B' are provided, respectively, also with the ribs or projections *a* and *c*. When the adjacent rails are brought together, the ribs *a* abut against the ribs *c*, thus fixing the proper alinement of the rails. These ribs *a* and *c* are not affected by the welding, since they are removed sufficiently far from the location of the welding not to be affected by it.

The upper surface of the plate B is provided with slight upward projections or contact-points *d*. These points are brought in contact with the bottom of the rail in proper position preparatory to welding. When the welding-current is turned on, it is localized at the points *d*, and only these points and the corresponding points of the rail are brought to a welding heat. As a consequence the weld is much more quickly made and with much less current than if the continuous upper surface of the plate B were brought in contact with the rail. This arrangement therefore is in the interest of economy and practicability. Perhaps a much more important consideration, however, is this: When the contact-points *d* and the corresponding points of the bottom of the rail have reached a welding heat and the plate B and rail A are rigidly clamped together to produce the weld, the intervening parts *e* of the upper surface of the plate B and the parts of the rail corresponding thereto have not been raised to a welding heat. Consequently when these parts come together the welding compression can force them no farther and therefore the parts *e* and the normal bottom of the rail are retained in perfect alinement with the upper surface *f* of the outer end *g* of the plate B. Thus provision is made for keeping the lower and upper surfaces of the adjacent rails in perfect alinement.

It is to be observed that the contact projections *d* are placed only on the inner or welding end of the plate B, the outer end *g* of said plate being free from such projections.

The plate B is provided at or near its inner end and at the bottom with the inwardly-projecting lug or support *h*, and the plate B' is similarly provided with the supporting-lug *h'* at its inner end.

Now when the rails A and A', with their respective plates B and B', are brought together in forming a joint, as shown in Figs. 8 and 9, the lug *h'* of the plate B' supports the free or outer end of the plate B, and in like manner the lug *h* of the plate B supports the free or outer end of the plate B'. Thus each rail is supported close to the junction of the two rails by the girder-plate welded to the bottom of the adjacent rail, and each rail, in addition, is supported, through the girder-plate welded thereto, by the lug at the extreme inner end of the girder-plate welded to the adjacent rail, that is, each rail is supported far beyond its outer end by the lug on the inner end of the girder-plate welded to the adjacent rail. This forms an interlocked or trussed joint which in itself gives an enormous support to the ends of both rails.

The bolt-holes in the plates B B', or some of them, are oblong in shape to allow for the proper expansion and contraction of the rails, and in forming the joint these plates are preferably securely bolted together, as shown in Figs. 19 and 20.

To further enhance the efficiency of the joint, the fish-plate C is welded to the side of the rail A, one end of said fish-plate being welded in the side groove of said rail and the other end projecting beyond the end of the rail, as shown in Figs. 13 and 14.

The fish-plate C is provided on its inner side with the projections *i* near the upper and lower edges of said plate.

When the plate C is placed in the groove of the rail in position to be welded, these projections *i* find a bearing against the rail adjacent to the upper and lower corners of the groove of the same. The projections *i* are normally long enough to keep the main body of the plate C a short distance away from the rail. As soon, however, as the welding-current is turned on it quickly brings the projections *i* and the parts of the rail touched by them to a welding heat. The clamp is now applied to press the plate C and rail together to complete the weld, as shown in Figs. 13 and 14.

It will be seen that the upper and lower edges *k l* of the plate C intervening between the projections *i* are not brought to a welding heat, and consequently the pressure exerted in welding brings these edges up to a close-fitting position against the flange and head of the rail, as shown in Fig. 14, but does not interfere with the proper alinement of the edges of the plate C throughout any part of their entire length. As a consequence when the plate C is welded to one rail its outer or free end will fit exactly into the groove of the adjacent rail and the two rails will be in exact alinement.

It will be noted that if the whole surface of the upper and lower edges of the plate C in contact with the rail were brought to a welding heat the welding pressure on the plate C would be liable to press the welded end out of alinement with the free end, and consequently the adjacent rails when brought together would be out of alinement.

The construction shown in Figs. 15, 16, 17, and 18 is identical with that described in connection with Figs. 11, 12, 13, and 14, but applied to the adjacent rail. It is not necessary, therefore, to specifically describe these figures.

The completed joint is shown in Figs. 19

1074

and 29, in which the rail A, provided with the welded plates B and C, and the rail A', provided with the welded plates B' and C', are brought together. The outer or free ends of the plates B and C overlap the rail A' and the free ends of the plates B' C' overlap the rail A.

Bolts passing through the plates B B' and through the plates C C' and the rail hold the parts firmly together, forming a perfectly-trussed joint, the rails in perfect alinement in all directions and with proper provision for the expansion and contraction of the rails.

The rails are supported on ties or in any usual or suitable manner not necessary to illustrate.

If desired, the upper and lower projections *i* on the plate C might be joined together, forming a welding-rib across said plate, as shown in dotted line in Fig. 16, but I prefer the arrangement of small independent projections to facilitate rapidity of welding, economy of current, and in order to have several small welding-spots distributed over the rail rather than to have any single larger surface of the rail brought to a welding heat, since the latter would be liable to deteriorate the rail. For the same reason I prefer to put the upper and lower projections *i* diagonally opposite each other, as shown, rather than directly opposite each other. By thus "staggering" the welding-points I avoid such weakening of the rail as might occur by having more than one small welding-point in the same vertical plane of the rail.

Having thus described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. In a rail-joint, a plate having one end permanently secured to the bottom of one rail, space being left being between said plate and the longitudinal center of said rail, the opposite end of said plate extending under and detachably supporting, the adjacent rail, substantially as described.

2. In a rail-joint, the combination, substantially as described, of two rails, each provided with a truss or plate having one end permanently secured to the bottom of said rail at one side of the longitudinal center of the same, and the opposite end extending under and supporting the adjacent rail, an open space being thus left between the inner vertical walls of said truss or bottom plates.

3. In a rail-joint, the combination, substantially as described, of the rail and a girder or truss plate having one end permanently secured to the bottom of said rail and the other end extending beyond the end of said rail and detachably supporting the adjacent rail, said plate being provided with ribs or projections extending inwardly toward or under the longitudinal center line of the rail and affording central support for the same.

4. In a rail-joint, the combination, substantially as described, of two rails, each provided with a truss or plate having one end permanently secured to the bottom of said rail at one side of the longitudinal center of the same, the other end of said plate extending beyond the end of said rail and forming a support for the adjacent rail, said plates being provided with vertical ribs or projections extending inwardly toward or under the center of the rail and arranged to afford central support for the same.

5. The girder-plates B B' adapted to be secured to the bottoms of adjacent rails, said plates being provided, respectively, with the inward projections *b b'*, said projections alternating with each other, substantially as described.

6. In a rail-joint, a splice-bar constructed for welded attachment to one only of the abutting rails, said bar being provided with a plurality of welding projections grouped nearer to one end of said bar than the other and adapted to form a plurality of welding connections with the same rail, substantially as described.

7. In a rail-joint, the truss or bottom plate B provided with the welding projections *i* with space between them, said projections being adapted to form several welding connections with the same rail, substantially as described.

8. In a rail-joint, a splice-bar constructed for welded attachment to one only of the abutting rails, said bar being provided with a plurality of welding projections grouped nearer to one end of said bar than the other, said projections forming a plurality of welding connections with the same rail, the position of said splice-bar between said projections, and not raised to a welding heat, limiting the compression and regulating the predetermined relative position of said splice-bar and rail when welded together, substantially as described.

9. In a rail-joint, a splice-bar provided with a plurality of welding-points projecting from the surface of said bar and grouped nearer to one end of said bar than the other, portions of said bar being located between said welding projections and not raised to a welding heat, limiting the position of said bar and causing the same to fit the surface or groove of the rail in a predetermined manner, whereby said splice-bar, when welded to the rail, will be in proper and exact alinement relatively to the rail or rails, substantially as described.

10. A splice-bar provided with welding-points projecting from its surface, said welding-points being located at intervals diagonally opposite to each other, substantially as described.

11. A rail-joint consisting, essentially, of the following elements in combination: two abutting rails, each provided with a truss plate having one end permanently secured to the bottom of said rail and the opposite end extending under and supporting the other rail, space being left between the inner vertical sides of said plates, said girder-

COPY BOUND CL

interlocking and detachably supporting each other, fish-plates on opposite sides of said rails and bolts passing through said fish-plates and rails.

12. A rail-joint consisting, essentially, of the following elements in combination: two abutting rails, each provided with a truss-plate having one end permanently secured to the bottom of said rail and the opposite end extending under and supporting the other rail, space being left between the inner vertical sides of said plates, said girder-plates interlocking and supporting each other, and two fish-plates, each rail being provided with one having one end permanently secured to the side of said rail and the other end overlapping the abutting rail, said rails being detachably secured together.

ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 616,436, dated December 20, 1898.

Application filed February 7, 1898. Serial No. 669,352. (No model.)

To all whom it may concern:

Be it known that I, HENRY F. A. KLEINSCHMIDT, of Johnstown, in the county of Cambria and State of Pennsylvania, have invented new and useful Improvements in Electric Welding, of which the following is a full, clear, and exact description, reference being had to the accompanying drawings, which form a part of this specification.

This invention (Case A) relates to electric welding; and it is my object to provide a novel method for the same by which I am enabled to effect a highly-efficient weld without deteriorating the qualities of the steel and without subjecting the same to severe cooling strains.

The apparatus which I have shown and will describe by which my method can be put into effect is especially applicable for welding splice-bars to rails for the construction of what is known as "continuous railway-track:" but as my invention is also applicable for welding other products I do not desire to limit myself to the welding of continuous rails.

Ordinarily methods of welding tend to destroy the toughness of the metal, because the high heat renders the metal crystalline, and the subsequent upsetting causes the coarse crystals to separate and weaken their hold upon each other. In certain classes of welding, such as when a member is welded to the side of a rail, very severe strains are set up in the rail by the irregular heating and cooling and the sharp local contrasts in the temperature of the metal. This often causes the rail to break below its normal strength. In this same class of welding the burning of the metal under high heat often leaves cavities therein, which are not effectually closed by the ordinary process of upsetting. My invention is designed to obviate all of these troubles; and it consists in upsetting and simultaneously compressing the metal as soon as it is heated to the desired temperature and then retaining said metal under compression and in contact with cold metallic surfaces until the metal has become sufficiently cold to be deprived of nearly all of its plasticity.

Referring to the drawings, Figure 1 shows an apparatus for welding continuous rails in the street. Fig. 2 shows a splice-bar which is well fitted for use with my improved method. Fig. 3 shows a cross-section of a completed weld between two splice-bars and a rail, taken on a line which would pass through one of the bosses *b*.

A is the rail to which the splice-bars are to be welded.

B are the splice-bars.

C is a stationary electric transformer, having terminals C', adapted to engage the outside of the splice-bars.

D are arms which engage the back of the terminals C', are pivoted at *d*, and are connected at their upper ends to plungers d', moving in a cylinder d^2, which receives water through pipes d^3, connected with a hand-pump d^4.

In welding the bosses *b* to the rails the splice-bars are laid against the side of the rail and the terminals C' brought to the position shown in Fig. 1. Current is then passed transversely through the rail and the splice-bars until a suitable temperature has been reached, when the pump d^4 is operated and the terminals C' moved toward each other with a heavy pressure. The bosses *b* extend only a very short distance from the main body of the bar, so that they will not prevent the bar from making close engagement with the rail and so that any tendency which they may have to bulge out will be prevented by the rapid cooling and compression to which they are subjected. After upsetting such a weld, whether with light o. with heavy pressure, it has been usual to immediately relieve the pressure and remove the transformers from their contact with the bars. In accordance with the present invention, however, the pressure is retained at its maximum for a considerable time, and I have found that this is of the utmost importance. This time will vary under different conditions but should last until the temperature has fallen sufficiently to remove any considerable degree of plasticity. I find that it is usually safe to remove the pressure if the temperature has fallen sufficiently so that there is practically no glow given off by the cooling metal.

In the specific case shown the rail is about

1078

six inches high and is about eight square inches in cross-section. The pressure used is about twenty-five thousand pounds, and it is necessary for the best results to retain the metal under this compression for about two minutes after the heating-current has been shut off. I do not, however, desire to limit myself to these specific details, which I have only set forth as showing what I have found a preferred length of time for a particular form and size of weld.

I do not lay claim in this application to the form of splice-bar which I have shown and described, for this forms the subject-matter of an application for Letters Patent filed by me of even date herewith and serially numbered 669,353.

What I claim, and desire to protect by Letters Patent, is—

1. The method of electrically welding bars to the sides of rails which consists in passing the heating-current transversely through the bars and rail, forming the weld by laterally compressing the bars against the rail, and retaining the bars continuously under compression and in contact with relatively cold metal surfaces until said bars have cooled sufficiently to substantially remove their plasticity.

2. The method of electrically welding bars to the sides of rails which consists in passing the heating-current transversely through the bars and rail, forming the weld by laterally compressing the bars against the rail, and retaining said bars continuously under compression and in contact with cold conducting surfaces until they have cooled sufficiently to have lost substantially all appearance of glow.

In testimony whereof I have affixed my signature in presence of two witnesses.

UNITED STATES PATENT OFFICE.

GEORGE D. BURTON, OF BOSTON, MASSACHUSETTS.

ELECTRIC METAL-WORKING APPARATUS.

SPECIFICATION forming part of Letters Patent No. 647,694, dated April 17, 1900.

Application filed August 11, 1898. Serial No. 688,382. (No model.)

To all whom it may concern:

Be it known that I, GEORGE D. BURTON, a citizen of the United States of America, residing at Boston, in the county of Suffolk, in the State of Massachusetts, have invented certain new and useful Improvements in Electric Metal-Working Apparatus, of which the following is a specification.

This invention relates to electric metal-working apparatus for the forging, welding, and brazing of metals and for heating metal articles, such as wheel-tires, for the purpose of setting them.

The invention is especially adapted for lap-welding by the use of a primary transverse current. The lap weld is superior to the butt-weld. No end pressure is required, and consequently there is no upsetting of the metal and no formation of a bulge or projection at the joint, which is afterward required to be filed or hammered down.

The object of the invention is to provide a simple, convenient, and compact apparatus for the use of a blacksmith or other metal-worker.

Figure 1 of the accompanying drawings represents a perspective view of this apparatus. Fig. 2 represents, on an enlarged scale, a front elevation of the rotary electrode-head, having a plurality of electrodes for a variety of purposes, and a vertical longitudinal section of a portion of an anvil supporting the opposite electrode, a piece of work to be lap-welded being disposed between the electrodes. Fig. 3 represents a longitudinal section of an anvil-electrode and a fragment of one of the wheel-electrodes adapted for countersinking screw-holes. Fig. 4 represents a transverse section thereof. Fig. 5 represents a vertical section of anvil and wheel electrodes, clamping between them a section of a grooved metallic portion of a vehicle-tire adapted for receiving a rubber tire. Fig. 6 represents a perspective view, preparatory to lap welding, of the lapping ends of the metallic portion of a vehicle-tire adapted to receive a rubber tire. Fig. 7 represents a vertical longitudinal section of wheel and anvil electrodes adapted for lap-welding the joint between two pipe-sections of different sizes. Fig. 8 represents a transverse section thereof. Fig. 9 represents a longitudinal vertical section of wheel and anvil electrodes adapted for brazing or welding a longitudinal slit in a metallic tube. Fig. 10 represents a transverse section thereof. Fig. 11 represents a longitudinal vertical section of anvil and wheel electrodes adapted to form a lap-weld between two bars of metal. Fig. 12 represents a transverse section through the lap-weld joint. Fig. 13 represents a vertical longitudinal section of one end of the anvil and of wheel and anvil electrodes adapted for riveting.

The same reference-numbers indicate corresponding parts in all the figures.

The electric current for use in this apparatus may be taken from any suitable source of electricity. I have devised for this purpose a dynamo-electric generator of peculiar construction which has a wide range of current as regards both amperage and voltage and which will supply a primary current of large volume and low voltage, thus avoiding the use of a transformer. The dynamo 20 herein illustrated is of this sort; but as it will constitute the subject-matter for a separate application for a patent it is not deemed necessary to herein describe it in detail.

An exciter-dynamo 90 is employed in connection with the generator-dynamo 20 for exciting the field of the latter, said exciter-dynamo being properly connected with the field-magnets of the generator by wires (not shown) and a rheostat being arranged in the field-circuit of the exciter for regulating the excitation of the field of the generator, as in United States Patent No. 475,232 to Burton, Eddy, and Briggs, dated May 17, 1892.

A bed-electrode 100, constituting one of the working terminals of the circuit, is supported on an anvil, as the blacksmith is accustomed to the use of the anvil and this arrangement suits his convenience, and the loss of heat incident to the transferring of the work from the ordinary forge to the anvil is avoided. The anvil herein shown consists of an ordinary anvil 110, which is provided at its rear end with a square vertical slot 111 and a round vertical slot 112. In this instance the round slot is shown as the one utilized for connecting the bed-electrode with the anvil. For this purpose the bed-electrode 100, as shown in Figs. 1 and 2, comprises a block of highly-conductive material, such as copper,

1082

provided with a downwardly-projecting stud 101, which extends through the hole in the anvil. The lower end of this stud is screw-threaded, and the nut 102 operates to clamp the electrode to the anvil. Any other suitable means may be employed for fastening the electrode to the anvil. The electrode is preferably insulated from the anvil by any suitable insulating material 103, such as fiber board or mica; but it is not absolutely necessary to provide this insulation, as the current used is low in voltage and the conductivity of the electrode is much higher than that of the anvil. This electrode is provided with a socket 104, having a binding-screw 105, and a conductor 120, which may consist of a bar of copper, connects said electrode with one pole of the generator-dynamo. A switch-block 130 is connected by conductor 140, also preferably composed of a bar of copper, to the other pole of the generator-dynamo.

An arm 150 is hinged to the switch-block 130 and carries at its free end a rotary electrode-head 200, having a plurality of radial arms, as 210, 220, 230, 240, 250, and 260, said arms carrying electrodes of different shapes adapted for different purposes. The electrode-head 200 is clamped to the hinged arm 150. The arm, as shown, is provided with a lateral stud 151, on which the hub of the electrode-head is adjusted, and a clamping-nut 152 on said stud holds said electrode-head in place. The electrode-head may therefore be readily removed, and another having electrodes of different shapes may be substituted therefor. An elastic support is provided for said arm, preferably in the form of a spring 170, having one end connected with a bar 160, extending from the switch-block, and connected at its other end with the hinged arm 150. This spring serves to normally support the hinged arm in such position that the electrodes of the electrode-head 200 will be above the electrode 100 on the anvil. The hinged arm is composed of conductive material, and the spring is insulated therefrom. A foot-lever 180 is hinged to the anvil or at any suitable point, and a connecting-rod 190 is connected at its upper end with the conductive hinged arm 150 and at its lower end with the foot-lever. This connecting-rod is insulated from the hinged arm. A spring 183, connected with a bracket 181 and with the foot-lever, tends to hold the foot-lever in elevated position. The spring 170 for supporting the hinged arm 150 is preferably so adjusted as to hold the arm in such position that the electrodes on the rotary head are held normally out of contact with the bed-electrode 100 on the anvil and to lift said electrode out of contact with the work when the foot lever is released.

The bed-electrodes 100 are made in a variety of shapes and are interchangeable to correspond with the electrodes of the electrode-head 200 for different kinds of work.

In the use of this apparatus the pieces to be lapwelded are adjusted or placed with their ends overlapping on the bed-electrode 100. Then the foot-lever is depressed, and one of the electrodes of the electrode-head is brought into contact with the work, whereby the circuit is closed and the current passes through the work in transverse direction across the overlapping ends of the parts to be heated. The current may pass in either direction from the generator and effect the result equally well. As soon as the piece is heated to the proper temperature, which may be ascertained by inspection thereof, the operator releases the foot-lever and the spring 170 lifts the hinged lever 150 and takes the upper electrode out of contact with the work, whereby the circuit is broken. Then the operator may shove the work forward on the anvil and hammer the joint or otherwise finish it, as desired. In this way the heating can be quickly and conveniently effected on the anvil without loss of time and heat and without forming an objectionable bulge in the work.

Any suitable block or bench capable of use in hammering, forging, or finishing metal may be considered as the anvil.

I claim as my invention—

1. In an electric metal-working apparatus, the combination of an anvil provided with a slot, a bed-electrode supported on said anvil and provided with a stud engaging said slot, said electrode being connected with one electric pole, and a swinging electrode supported above said bed-electrode and connected with the other electric pole.

2. In an electric metal-working apparatus, the combination of an anvil, a bed-electrode supported on said anvil and connected with one electric pole, a swinging arm carrying an electrode connected to the other electric pole, a rigid arm supported above said swinging arm, a spring connecting said rigid arm with said swinging arm and imparting an elastic support thereto, and a foot-lever connected with said swinging arm for swinging it into operative position.

UNITED STATES PATENT OFFICE.

JOHN C. PERRY, OF CLINTON, MASSACHUSETTS.

METHOD OF ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 670,808, dated March 26, 1901.

Application filed September 16, 1899. Serial No. 730,554. (No specimens.)

To all whom it may concern:

Be it known that I, JOHN C. PERRY, of Clinton, in the county of Worcester and State of Massachusetts, have invented certain new and useful Improvements in Methods of Making Welds Electrically, of which the following is a specification.

This invention relates to a new and improved method for making welds electrically.

Reference is to be had to the accompanying sheet of drawings, forming a part of this specification, in which like characters of reference are used to indicate like parts wherever they occur.

Figure 1 represents in side elevation a section of a machine embodying my invention and shows a transformer, the pressure device, and the switches, and also the connecting-wires for completing the primary circuit. Fig. 2 represents in side elevation a detailed view of the machine, showing the position of the automatic switches after the completion of the weld. Fig. 3 is a substantially similar view showing the plunger in position to reset or lock in position the automatic circuit-breaker. Fig. 4 represents two parts when being welded together, with the envelop of vapor surrounding the joint exaggerated for the purposes of illustration. Fig. 5 shows the parts after the weld is completed. Fig. 6 represents two spherical bodies in the act of being welded. Fig. 7 shows the same when the weld is completed.

By my invention the welds are made instantaneously without any appreciable heating of the material adjacent to the point of the weld, and my improved method consists in the simultaneous application to the parts to be joined or welded of a mechanical pressure nearly equal to the crushing strength of the material and a current of electricity of relatively enormous volume. By using a mechanical pressure nearly equal to the crushing strength of the material I insure the parts being forced together the instant they soften, and by the employment of a current of electricity of relatively enormous volume compared with the area of contact of the parts to be welded I am enabled to produce an instantaneous heating or softening of the metal. The welding-current is much stronger than has heretofore been considered suitable, being from one to two hundred thousand amperes to a square inch, while the mechanical pressure of the electrodes for forcing the heated parts together is nearly equal to the crushing strength of the material being welded when cool. As a result of this the parts to be welded are first brought into intimate contact, and immediately thereafter the circuit is closed between the electrodes. The current is of such strength that the contacting parts of the said members become heated to a fusing-point immediately, and as soon as the metal sufficiently softens, so that its resistance is less than the force of the compression spring or weight, such spring or weight forces the movable electrode farther toward the stationary electrode to weld the parts together. Immediately after this compression the circuit is broken and before the heat is spread away from the contacting surfaces. Consequently the metal cannot be overheated or blown out. As the electrodes are relatively of large volume or area compared to the contacting metal to be welded, there is no necessity for artificial cooling. Further, by my invention two parts covered with a coating of metal fusible at a lower temperature than said parts can be readily welded—as, for instance, iron wire covered with a coating of zinc, as shown in Figs. 4 and 5. When the said parts to be welded are brought into contact, their contacting surfaces are of a relatively small area at the beginning of the operation and the area increases as the metals are compressed together.

It is obvious that since the coating of the parts to be joined is fusible at a temperature lower than the fusing-point of the body coated thereby said covering will be volatilized if the welding operation consume any considerable portion of time, and the covering at the weld will be removed and in case of iron the exposed part liable to rust. In accordance with my invention, however, the weld is practically instantaneous and the heat is localized at the point of contact between the two parts, so that only the coating at the point of contact is volatilized or disturbed, thus forming an envelop surrounding the weld, as portrayed in Figs. 4 and 6, to prevent access of air thereto and consequent oxidation, the rapidity of the weld being such that the heat

does not spread through the coating over such surfaces as are not brought into contact and welded together. The circuit is broken immediately upon the completion of the weld, so that the envelop of gas or vapor is chilled instantaneously and a portion of the said coating material is redeposited at the joint, oxidation being prevented by the outside portions of this vapor or gas. When heavy welds are made by this process, so that the fillet or bur of highly-heated metal is forced out of the joint, it is covered when of iron by a thin film of magnetite or magnetic oxid and is rust-proof.

As stated, in following out my process or method all of the contacting portions of the electrodes are made very large to permit the flow of the heavy current over the parts to be welded without injuring the covering of zinc or other material and also to assist in keeping the parts adjacent to the weld cool. By my invention the joints formed by the weld when the parts have the described coating are fully covered and protected by the zinc covering, for when two bodies covered with a coating fusible at a relatively low temperature are welded together by my method the covering is practically uninjured about the joint, and the joint is thus rust-proof. Further, by my invention two parts (of which one is under tension) can be readily welded, for, although the abutting or contacting portions thereof reach a high temperature for an instant, the heat is localized about said surfaces and does not extend through the entire body of the said parts, thus preventing the body from being stretched, elongated, or bent at the weld or dominated by the described stress or strain, as would be the case if the welding operation were continued, as was done prior to my invention, over such a period of time that the entire body of the metal became heated and softened, so that it would be affected by such stress or strain, for by my invention merely the contacting surfaces are softened.

While my invention may be carried out in many ways, I prefer for simplicity of construction the means shown in the drawings, which are herein illustrated in order to disclose the mechanism by which my improved method may be practiced.

a represents a part of the framework of the machine, said frame being formed in any desirable way and supported upon suitable legs or standards; but inasmuch as the construction of the framework forms no material part of my invention it is unnecessary to describe it in detail.

b indicates a shaft which is driven in any suitable way and on which is secured a path-cam *c* and also a cam *d*. The path-cam actuates a lever *e*, fulcrumed at *e'* on a bracket *a'*, forming a part of the framework, said lever being constructed and arranged to cause the actuation of a movable electrode *f*. Said electrode *f*, together with that indicated at *g*, is mounted in a suitable manner upon and insulated from the framework. The brackets *f' g'*, which support said electrodes, form a part of the secondary circuit (indicated at *h*) and the primary circuit, including the coils *i* and the wires i^2 i^3 i^4. The movable electrode *f* is connected to the upper end of the lever *e* by a connecting-rod f^2, which is slotted at its end to receive the pin f^3, passed crosswise through the plunger, of which the movable electrode forms a part, and between the end of the plunger and a collar f^4, adjustably secured upon the rod f^2, there is a powerful compression-spring f^5.

When two parts to be welded together according to my invention are placed between the electrodes and the cam *c* actuates the lever *e*, the electrodes clamp the said parts with a pressure a little less than the crushing strength of the metal of which the parts are formed, the spring f^5 being compressed when the resistance of the said parts becomes greater than the strength of the said spring, and after the contacting surfaces of the parts become softened the spring f^5 instantly and automatically forces the said parts into intimate contact to complete the weld, as shown in Figs. 5 and 7, and thus automatically breaks the circuit.

I so arrange the apparatus that the primary circuit is closed immediately after the clamping of the parts between the electrodes, and the circuit is broken when the movable electrode is pushed forward after the metal has become sufficiently softened to complete the weld or pushed to the limit of its forward movement, the whole operation taking place in a very short duration of time and the weld being practically instantaneous.

The circuit-closer is actuated automatically from the shaft *b* by the cam *d*, and it consists of the switch-lever *j*, having a roller *j'* bearing against said cam *d* and having its other end adapted to bear against the sufficiently-yielding contact j^2. The movable contact or switch-lever *j* is fulcrumed on a bracket j^3, suitably mounted on the framework, while the yielding stationary contact j^2 is supported in a bracket j^4. It is understood, of course, that the brackets in the lever *j* are suitably insulated from the rest of the machine, being included in the primary circuit.

The circuit-breaker is operated automatically by the movable electrode, as previously stated, and comprises the following elements: An elbow-lever k is fulcrumed upon a bracket k', supported by and insulated from the bracket f', and it constitutes a movable contact being connected with the wire i^3, and consequently with the switch-lever *j*. The stationary yielding contact k^2 is supported upon and insulated upon the bracket k' and is electrically connected with the wire i^2. A spring k^3 tends to break the circuit or to move the movable contacts from the stationary contacts k^2; but this tendency of the springs is overcome or prevented by a second elbow-lever k^4, fulcrumed upon the bracket k' and

having a knife-edge k^3, which engages a similar edge k^4 on the end of one of the arms of the elbow-lever k. The lever k^4 has an arm projecting downwardly into the path of an adjustable screw f^4 on the movable plunger or electrode f, and the parts are so adjusted at the final movement of the movable electrode upon the softening of the parts to be welded that the adjusting-screw f^4 engages the lever k^4 and disengages it from the movable switch-lever k, so that it permits the spring k^2 to break the circuit by swinging the movable contact away from the stationary contact k^3.

Manifestly the parts of the mechanism before described may be variously modified, and my improved method may be followed in making welds of various kinds without departing at all from the spirit or scope of my invention, which consists, as heretofore stated, in the simultaneous application to the parts to be joined of a mechanical pressure nearly equal to the crushing strength of the material and a current of electricity of relatively enormous volume.

This invention, as stated, I believe to be broadly new with me, and I desire to claim and to be understood as claiming the same in the broadest possible manner.

Having thus explained the nature of my invention and described a way of constructing and using the same, though without attempting to set forth all of the forms in which it may be made or all of the modes of its use, what I claim, and desire to secure by Letters Patent, is—

1. The method of making welds electrically, consisting of the simultaneous application to the parts to be joined of a mechanical pressure nearly equal to the crushing strength of the material to be welded, and of a current of electricity of relatively enormous volume, and subsequently and automatically breaking the circuit.

2. The method of welding coated wire which consists in localizing the heat at the point of contact to form about the joint a protective envelop of gas from the coating at the point of contact, and completing the weld while the joint is protected by said envelop and before the coating about the joint is destroyed.

3. The method of electrically welding parts having a coating of a relatively low melting temperature, which consists in applying to said parts a relatively enormous pressure, applying a current of electricity to said parts at their point of contact of relatively enormous volume and arranging said pressure to automatically force said parts together after the material softens, and thereafter break the circuit to volatilize the coating at the point of contact, to form an envelop about the weld and complete the weld before the heating action extends beyond the point of the weld or joint sufficiently to destroy the coating surrounding the joint.

In testimony whereof I have affixed my signature in presence of two witnesses.

UNITED STATES PATENT OFFICE.

RUDOLPH M. HUNTER, OF PHILADELPHIA, PENNSYLVANIA.

METHOD OF ELECTRIC WELDING.

SPECIFICATION forming part of Letters Patent No. 690,958, dated January 14, 1902.

Application filed April 7, 1898. Serial No. 676,756. (No model.)

To all whom it may concern:

Be it known that I, RUDOLPH M. HUNTER, of the city and county of Philadelphia, State of Pennsylvania, have invented an Improvement in Methods of Electric Welding, of which the following is a specification.

My invention set out in this application (Case 304) has reference to the manufacture of sheet metal in long lengths by electric welding; and it consists of certain improvements which are fully set forth in the following specification and shown in the accompanying drawings, which form a part thereof.

Heretofore it has been customary to make long lengths of sheet-tin for roofing by connecting the smaller sheets end to end by folded joints; but this has objection from the fact that it forms a heavy seam and is not always proof against leakage. Furthermore, sheets of metal of this character cannot be employed in such industries as the manufacture of sheet-metal cans, pans, &c.

The object of my invention is to provide a method of making continuous lengths of sheet metal, plain, tinned, or coated, and adapted for roofing and general manufactures, the said sheets being without seams and liquid-tight throughout.

In carrying my invention into practice I first manufacture a series of sheets of iron or steel of the requisite width, and these I arrange, two or more, end to end and unite them by electric welding. The welded joints may be subsequently run through cold-plate rolls and the said welded joints rolled down to the same thickness as the rest of the sheet-plate. This sheet metal may then be coated or tinned and finally passed between planishing-rolls, if so desired. The welding of the sheets of iron or steel together is an important feature of my invention, and in carrying out this part of my improvements I provide one end of the sheets with a series of projections, which may be formed by dies and arranged in a transverse line at or adjacent to one end of the plate. When these projections are placed upon or in contact with the other end of the next adjacent sheet, we will have an electrical contact made between the two plates or sheets at a series of separate and preferably equidistant points and adapted for offering a very material resistance. When these plates are pressed into contact and a current of electricity passed from one plate to the other, the welding operation begins at each of the points of contact, and as the metal in the immediate vicinity of the projections on the two plates melts small lakes of molten metal are formed, which quickly spread and unite, making a full transverse weld. Under ordinary conditions of simply lapping the edges and passing a current through from plate to plate the welding would be a failure, since it is impossible to properly control the action of the current and portions would melt and flow away before other parts are welded at all. By my improved method, however, I set up a simultaneous series of gradually-extending welds, which ultimately unite, and thus make it possible to properly unite the two sheets. When the weld is being made, the plates are pressed together as the metal becomes fused. Broadly considered, my invention comprehends the union of two sheets of metal in this manner irrespective of the purposes to which it may subsequently be put.

My invention will be better understood by reference to the accompanying drawings, in which—

Figure 1 is a side elevation of a sheet-metal-welding machine embodying my invention. Fig. 2 is an enlarged sectional elevation of a portion of same. Fig. 3 is a longitudinal section of the lapped sheets before welding. Fig. 4 is a plan view of a portion of same. Fig. 5 is a cross-section of same on the line of the projections. Fig. 6 is a plan view of a long sheet in process of being made by my process. Fig. 7 is an elevation showing my complete apparatus for welding, rolling, and coating diagrammatically. Fig. 8 is a sectional elevation of a apparatus for preparing the ends of the sheets before being welded. Fig. 9 is a longitudinal section of the welded sheets. Fig. 10 is a similar view of the joint after cold-rolling. Fig. 11 is a similar view after the plate has been coated or tinned, and Fig. 12 is a plan view of a modified form of plate-joint for welding.

A is the welding-machine for uniting the sheet C to the rear end of the sheet B. The

1089

long length of sheet metal comprises the portion B', which is fed in the form of a loop by feed-rolls D' and has its joints welded, as indicated at *d* in Fig. 9, and the portion B^2, which has passed through the cold-press rolls D and has its joints reduced to the condition of *f*, Fig. 10, having a uniform thickness with the rest of the sheet. The sheet so prepared may then be coated or plated in any suitable or well-known manner. In Fig. 7 I have shown it as being fed through a bath E of acid to cleanse it and thence through the tinning or galvanizing bath E'. The excess of the coating metal is rubbed off by the rolls *e*, and after cooling it may pass through planishing-rolls F. It is evident that the bath E' may be an ordinary copper-plating bath, if so desired, as will be well understood. The loop B' enables the sheet to be continuously drawn through the press-rolls D and permits the intermittent action of the welding-machine. The rolls D' act as a support arranged in alinement with the face of the horizontal press-rolls D and intermediate of said rolls and the welding means. The loop B' compensates for any variation in the length of the sheet between the welding-machine and press-rolls. It also secures a regular and uniform action in the baths E E'. The coating material, whether it be paint, size, tin, or copper, is indicated in Fig. 11 at K.

I will now describe the welding mechanism. The cylinder A is journaled in a main frame G, and the new sheets to be added are guided by a table N and fed under the clamp H. The clamp H is pivoted at *h* to an arm J, which is in turn pivoted concentrically with the axis of the cylinder A.

I is a block of slate carried on a spring-arm *i*, secured to the clamp H and is adapted to normally be held down below the clamp, so as to act as a stop or guide to receive the end of the metal sheet C to be welded and at the same time hold down the rear end of the previous sheet B. Pivoted at *h* on the end of the arm J is a head O, having a rear arm provided with a roller *r*, adapted to run under the guide R on the main frame, and a forward arm furnished with a set-screw *s* to limit the upward movement of the clamp H. A spring S is interposed between the rear end of the clamp H and the head O under the roller *r* and operates to throw up the clamp and guide on the return stroke and also to make the roller *r* follow the cam R.

L is a second pivoted arm, having its pivot concentric with the arm J and cylinder A. This arm L is adapted to be rocked or reciprocated by hand. It is provided with a stop L', which acts upon the arm J, so that when the arm L is pulled back it draws the arm J with it.

M is a cam pivoted to the arm L and is pressed downward by a spring *m*. In the positions shown in Fig. 1 a stop *j* acts to limit the movement of arm J, and a stop *l* may be used to limit the arm L, though this is hardly necessary in view of the use of the stop L'. The parts J, L, and R are insulated from the main frame.

P is a snap-switch for opening the electric circuit and is operated by a rod *p*, connecting with the arm L. This snap-switch consists of two arms pivoted together and having their free ends connected by a spring. One of the arms is connected with the rod *p*, and the other acts as the circuit-closing contact. When the arm L is moved to the right, the rod *p* is moved to the right until the spring passes beyond the pivot of these arms, when the spring snaps the lower arm over into the dotted position to open the circuit. In closing the circuit the reverse operation occurs.

P' is a circuit-closing switch, part being on arm J and part on arm L.

The electric current from an alternating-current dynamo *t* is transformed by a transformer or induction-coil T into a current of very low tension and great volume, and this is delivered to the main frame G or cylinder A and to the arm J by switch P' and circuit *n*, including the switch P.

The forward ends of the sheets C are prepared in the following manner: The edge is trimmed by shear *g*, and the surface near that edge is formed with a series of projections *b* on one side and depressions *c* on the other, as shown by dies *k*, Fig. 8, or in any other suitable manner. When this end of the sheet C is placed upon the rear end of plate B, we have the construction shown in Figs. 2, 3, and 5. It is evident that the die and shear shown in Fig. 8 may be arranged at N, Fig. 1, in proper position to secure the proper feeding of the sheet.

The operation of the welding-machine will now be understood. The parts being in the positions shown in Fig. 1, the sheet C is thrust in upon the end of the sheet B. The arm L is then moved to the right, causing the cam M to ride over the clamp H and press it firmly down upon the plate C with an elastic pressure. The parts are then in the position shown in Fig. 2. In coming to this position the arm L moves the switch P' to close the secondary circuit *n*, causing the electric current to pass between H and A and between the plates B C by contacts *b*. As the arm L is moved farther to the right its upper part strikes the forward part of the head O and moves the arm J backward. The roller *r* passes under the cam R, compressing the spring S and raising stop *s*. When the welding is completed, the arm L opens the snap-switch P and is then moved to the left. This action releases the clamp H from the cam M, and under the effect of the spring S the clamp H is moved away from the cylinder A. At this time the weld is as shown in Fig. 9. The clamp has raised sufficiently to clear the guide-stop I of the forward edge of sheet C. The movement of the arm L to the left moves the arm J with it through part L', and the several portions of the apparatus return to the posi

tions shown in Fig. 1. The sheet B, with the addition C, is then moved under roller A' and through feed-rollers D', and the operation is repeated with a new sheet. When the arm L first moved to the right to operate the clamp H by the cam M, it immediately closed the switch P' and put on the current. When a small movement to the right of both arms L and J was made, the switch P automatically snapped open to break the current to stop the welding. In the reverse movement the arm L opens the switch P' and subsequently closes the switch P to bring them into position for a new operation. As the welding operation takes place the pressure of the spring *m* causes the clamp H to force the plates C B together as the projections *b* become fused into the surface of the plate B.

An overload-switch Q may be employed to automatically open the circuit when the maximum current flows, so as to prevent any possibility of the lapped body portion of the sheets becoming melted or fusing. The transformer T may be operated on constant-potential mains and have a maximum capacity which may accord with the capacity of the switch Q. This switch Q operates to open the secondary circuit *n* when a sufficiently large current passes through it, said current being dependent upon the resistance presented by the lapped sheets through which the current must pass. As the welding progresses the resistance of the joint decreases and more current flows in the circuit *n*. When this current reaches a maximum, the magnet of the switch Q operates its armature and releases the spring-actuated circuit-closing switch. This prevents abnormal fusing at the welded joint.

It is to be understood that in carrying out this welding operation my invention comprehends the same method whether the points of contact are upon the sides or edges or upon both plates, as the invention comprehends, broadly, the preliminary forming of points or surfaces of contact of less area than the whole surface to be welded and securing the welding operation by causing them to become fused as a preliminary operation to the complete weld. In this manner the weld may be made upon plates butted together, as shown in Fig. 12, the projections or points of contact being upon the edges of one or both plates. In this case the edges are pressed together, as in the other case, during the welding operation. Alternating or direct current may be used, as desired. Plates or sheets of metal united in this manner may be used as roofing-plates, in the manufacture of sheet-metal cans, boilers, tanks, and hardware generally.

If the transformer T is properly proportioned, the current may be just sufficient to produce the welding operation so long as the two lapped parts of the plates are not fully pressed together, and when this latter takes place by the welding the resistance will be so low that the current loses its power to fuse, and the lapped ends will not be melted off or injured. This will insure the process being automatic and adapted to take care of itself to avoid injury to the plates.

I do not confine myself to the details of construction of the apparatus for carrying my invention into practice, as these may be modified without departing from the spirit of the invention.

What I claim as new, and desire to secure by Letters Patent, is as follows:

1. The method of welding two wide thin flat sheets of metal together to form one continuous sheet which consists of first shaping the end of one or both sheets so as to produce a large number of small projecting portions arranged in line across the sheet or sheets, then overlapping the ends of said sheets so as to bring them in contact alone at a series of small points in the lapped surface of the sheets, then passing a current of electricity simultaneously through all of the series of small points of contact, simultaneously pressing the two sheets together as the metal about the points of contact melts whereby a large series of small fluid portions of metal are formed and gradually increased in area and separated by gradually-decreasing areas of solid or non-fluid portions until the several fluid portions just meet to form a long weld, and then arresting the current to prevent burning off of the ends of the sheets.

2. The herein-described method of electric welding of two wide and thin sheets of metal which consists in placing the two sheets in contact at a large number of small independent points arranged in the line of the weld transversely across the sheets, then passing a current of electricity simultaneously through the series of points of contact and pressing the two sheets together as the welding operation progresses, and continuing the said pressure until the several independent series of welds increase on all sides sufficiently to extend into each other to form one complete and long welded joint.

3. The method of forming a long sheet from two or more sheets of metal, consisting in producing a series of projections upon one of the sheets near its edge, lapping the two sheets so that they make electrical contact through the projections only, passing an electric current through the projections and both sheets, pressing the two sheets together as the weld advances, and finally passing the welded sheets through a pair of rolls to reduce the welded joint to the same thickness as the body of the sheets.

4. The method of forming a long sheet from two or more sheets of metal, consisting in producing a series of projections upon one of the sheets near its edge, lapping the two sheets so that they make electrical contact through the projections only, passing an electric current through the projections and both sheets, pressing the two sheets together as the weld

advances, passing the welded sheets through a pair of rolls to reduce the welded joint to the same thickness as the body of the sheets, and subsequently coating the continuous sheet with an outer covering as a protection to the metal forming the body of the sheet.

5. The method of forming a large sheet of metal from two smaller sheets, consisting in overlapping the adjacent ends of the sheets and holding them in contact at a series of points arranged in line across the sheet so that they are in contact for an area greatly less than the extent of surface required to constitute the completed weld, then passing an electric current through all of the portions of the sheets in contact, and as the welding proceeds forcing the two sheets into greater contact to reduce the electrical resistance and to cause the fluid places in the weld to spread toward each other.

6. The herein-described process of welding consisting in generating a current of electricity of uniform voltage and fixed maximum current, supplying this current to a large series of equally-distributed points of contact in multiple between two sheets to be welded of uniform sectional area and resistance throughout so as to offer a sufficient but subdivided resistance to secure the welding effect at a large number of points simultaneously, then pressing the two sheets together as the welding proceeds until the resistance becomes so low that the current will cease to be sufficient in volume to continue the welding after a given extent of weld has been made, whereby the union of the sheets is secured and the destruction of the lapped portions guarded against.

7. The herein-described process of welding consisting in generating a current of electricity of uniform voltage and fixed maximum current, supplying this current to a large series of equally-distributed points of contact in multiple between two sheets to be welded of uniform sectional area and resistance throughout so as to offer a sufficient but subdivided resistance to secure the welding effect at a large number of points simultaneously, then pressing the two sheets together as the welding proceeds until the resistance becomes so low that the current will cease to be sufficient in volume to continue the welding after a given extent of weld has been made, and automatically interrupting the current when the maximum current required is reached, whereby the union of the sheets is secured and the destruction of the lapped portions guarded against.

In testimony of which invention I hereunto set my hand.

UNITED STATES PATENT OFFICE.

SEBASTIAN ZIANI DE FERRANTI, OF GRINDLEFORD BRIDGE, SHEFFIELD, ENGLAND.

BLADED TURBINE ELEMENT.

No. 874,398. Specification of Letters Patent. Patented Dec. 24, 1907.

Original application filed May 14, 1904, Serial No. 208,034. Divided and this application filed July 22, 1907. Serial No. 385,056.

To all whom it may concern:

Be it known that I, SEBASTIAN ZIANI DE FERRANTI, a subject of the King of Great Britain and Ireland, residing at Grindleford Bridge, Sheffield, in the county of York, England, (late of 31 Lyndhurst road, Hampstead, London, N. W., England,) have invented a certain new and useful Bladed Turbine Element, of which the following is a specification.

The invention relates to the bladed elements of turbines and has for its object the provision of a bladed turbine element of exceedingly simple construction as regards the attachment of the blades so that caulking strips, lacing or wiring and other complex means employed for fixing the blades may be dispensed with.

A turbine element with the blades welded thereon has hitherto been a desideratum since such a bladed turbine element approaches closely to the ideal form shaped from a solid mass of metal. Difficulties, however, exist in the production of such a bladed turbine element partly on account of the blades and their carrying elements differing largely as regards their power of conducting heat away from the welding point and partly on account of the close juxtaposition of the blades. Thus it is found that the comparatively large volume of metal forming the carrier rapidly conducts heat away from the welding point and prevents the temperature of the carrier rising to the required extent. I overcome all these difficulties, however, by a process described in my patent application, Serial No. 208034, which consists broadly in adjusting the volume of the metal in the neighborhood of the welding point so that approximately equal heating occurs in both faces to be welded and passing electric current through the welding point.

I believe that I am the first to produce a turbine element with the blades directly welded thereto and such a bladed turbine element forms the subject matter of the present invention.

Referring to the accompanying drawings, Figure 1 is a part side elevation of a turbine wheel having cross grooves, Fig. 1ª being an edge view; Fig. 2 shows a similar edge view of a modification in which sets of intersecting grooves are adopted; Fig. 3 shows an edge view of a form having circumferential grooves, Fig. 3ª being a section on the line A A of Fig. 3. Fig. 4 shows, in longitudinal sectional elevation, part of a drum carrier to which the blades are welded in accordance with one form of the invention; Figs. 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disk, while Fig. 7 is a part side elevation in which holes are bored through from face to face of the disk. Fig. 8 shows a sectional plan of a form of wheel built up of two dished disks, held apart at their circumferential portions by distance pieces, Fig. 8ª being a scrap edge view to a larger scale; Fig. 9 is a similar sectional plan of a modified form of wheel built up of three disks, while Fig. 9ª is a corresponding scrap edge view also to a larger scale; Fig. 10 shows a part sectional elevation of a wheel built up of two comparatively thick disks having notched edges. Fig. 10ª being a scrap edge view, while Fig. 11 shows an edge view of a form of wheel built up of a series of "stepped" laminæ.

(It will be seen that all the edge views in the preceding figures are shown as developments for clearness of drawing and not as true projections).

In carrying out the invention according to the form shown in Figs. 1 and 1ª, the turbine wheel or disk is shown at *a*, cross grooves, *b*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded. The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disk, as is shown in Fig. 2, or by cutting circumferential grooves, such as *f*, completely round the edge (see Figs. 3 and 3ª).

Fig. 4 shows the invention according to one form applied to the case of a drum blade carrier, a^1; the drum is grooved circumferentially with grooves, f^1, the intervening collars of metal being then cross-cut to form projecting teeth, c^1, on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disk, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in Fig. 5, or arranged without particular reference to the position of the blades, (see Fig. 6).

In Fig. 7, a method is shown of removing

metal in the neighborhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disk at a radius slightly less than that of its outside edge.

The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficeint areas untouched to insure the mechanical strength in the welded joint.

Referring now to Figs. 8 and 8ª, a form of wheel is shown somewhat diagrammatically which is built up of two dished disks, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces, such as *l*, disposed at a radius somewhat less than the maximum radius of the disks, the blades, *d*, being welded in position on their outside edges.

Figs. 9 and 9ª show a type of wheel generally similar to that last described but having an intermediate plane disk, *m*, in addition to the two dished disks, *k*; a portion, *n*, of the hub, *o*, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the disks in their correct relative position may be adopted.

In Figs. 8 and 9, the dished disks, *k*, are indicated as secured to the hubs, *o*, by pressing the inner edges of these disks into grooves and subsequently burring over the hubs to hold the disks in place.

In the modification shown in Figs. 10 and 10ª, two dished disks, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to Figs. 1 and 1ª. Again, that portion of the disk carrying the blades may be built up of a set of thin laminæ, *r*, (see Fig. 11), the edges of which are notched as at *s*, the laminæ being assembled in such a way that the notches, *s*, are "stepped" with regard to each other, so that the intervening projections of metal may follow the shape of the turbine blades to be welded to them.

Instead of notching the laminæ, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In this invention, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

Having now described my invention what I claim as new and desire to secure by Letters Patent is:-

1. A turbine blade carrier having blades welded directly thereto.

2. A turbine blade carrier with blades attached thereto wholly by welding.

3. A turbine blade carrier having blades attached thereto by welds, certain working stresses on said blades being transmitted to said carrier through said welds.

4. A turbine blade carrier having blades attached thereto by welds, certain bending stresses due to impact of fluid on said blades being transmitted to said carrier through said welds.

5. A turbine rotor having blades attached thereto by welds, certain working stresses on said blades being transmitted to said rotor through said welds.

6. A turbine blade carrier having blades attached thereto by welds and recesses in the carrier in the neighborhood of said welds.

7. A bladed turbine element, comprising in combination a blade carrying element, the volume of the peripheral portion of which in the neighborhood of the point of attachment of the blades has been so adjusted as to retard flow of heat away from said point of attachment together with blades welded to said carrying element.

8. A bladed turbine element comprising in combination a blade carrying element from the peripheral portion of which metal has been removed in the neighborhood of the point of attachment of the blades so as to retard flow of heat away from said point of attachment together with blades welded to said carrying element.

9. A bladed turbine element comprising in combination a blade carrying element having depressed portions on its peripheral area with intervening portions raised relatively to said depressed portions and blades welded to said relatively raised portions.

10. A bladed turbine element comprising in combination a body portion, blade carrying members proper attached to said body portion by one face and having blades welded to an opposite face together with spaces intervening between said blade carrying members proper.

11. As a new article of manufacture, a bladed turbine element having a plurality of spaced blades attached to the periphery of said carrier by direct butt welds.

12. A bladed turbine element comprising in combination a blade carrying element having a circularly disposed aggregation of depressed portions alternating with relatively raised portions and blades welded to said relatively raised portions.

13. A bladed turbine element comprising in combination a body portion; a circularly disposed aggregation of blade carrying mem-

bers proper attached to said body portion by one face and having blades welded to an opposite face together with spaces intervening between said blade carrying members proper.

14. A bladed turbine element comprising in combination a blade carrying element having a plurality of raised portions regularly spaced along said carrying element and blades welded to said raised portions.

15. A bladed turbine element comprising in combination a circular blade carrying element having a peripheral portion, a plurality of raised portions regularly spaced along said peripheral portion and blades welded to said raised portions.

In testimony whereof, I affix my signature in presence of two witnesses.

UNITED STATES PATENT OFFICE.

ADOLPH F. RIETZEL, OF LYNN, MASSACHUSETTS, ASSIGNOR TO THOMSON ELECTRIC WELDING COMPANY, OF LYNN, MASSACHUSETTS, A CORPORATION OF MAINE.

UNITING THE COMPONENT PARTS OF COMPOSITE SHEET-METAL STRUCTURES.

No. 928,701. Specification of Letters Patent. Patented July 20, 1909.

Application filed February 24, 1905. Serial No. 247,081.

To all whom it may concern:

Be it known that I, ADOLPH F. RIETZEL, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, (with post-office address Lynn, Massachusetts,) have invented certain new and useful Improvements in Uniting the Component Parts of Composite Sheet-Metal Structures, of which the following is a specification.

My invention relates to the manner of uniting or fastening two pieces of metal to one another and its object is more particularly to afford a substitute for the manner of uniting pieces of metal as heretofore practiced in the art of electric welding.

As applied to sheet metal manufactures the object is to afford a cheap and practical substitute for riveting and other methods of mechanically securing the two pieces of metal together. As applied to this branch of the metal working arts, the invention affords a means whereby articles of composite sheet metal manufacture may be made up by fastening the pieces of metal constituting the structure with a perfectly secure union and by a process that can be economically conducted.

Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots.

By the terms "weld" and "electric weld", as herein employed, I refer to that process of welding in which the metal is brought to plastic condition by passing an electric current from one to the other of two pieces where they are in contact and is welded while in such condition by the application of pressure, as contra-distinguished from a process of uniting metals, which is described in a patent to Bernardos, No. 363,320, dated May 17, 1887, and in which the union is effected by melting the metal by an arc and which is different from "welding" in the ordinary sense of the term as applied to metal manufactures, in that the metal is heated beyond the point of plasticity and pressure is not employed.

It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces. It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces. A weld formed according to my invention is distinguished however from such prior welds by the fact that the opposed surfaces are welded together in spots only, the heating electric current being localized or confined in any desired way to such spots so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together.

My invention is particularly valuable in fastening of pieces of sheet metal together because not only does it limit the amount of electric energy required very considerably as compared with the prior methods of union, but it also diminishes the liability to burning of the metal which is liable to occur when the attempt is made to form a union of two sheets of metal by an electric welding process over substantially the whole area of the meeting or opposed surfaces.

In carrying out my invention any desired number of spots of union may be employed, such number depending obviously upon the extent of the meeting surfaces which are to be fastened together and also upon the strength of the union desired.

In carrying out my invention the localization of the flow of heating electric current and of welding pressure to the desired spot or spots may be brought about in any desired way. One of the preferred ways is by providing between the meeting surfaces or portions of the pieces to be united suitable conducting projections or points at the spots of union, which projections or points carrying the heating electric current from one piece to the other are so located in the meeting surfaces and are so separated from one another that on the application of the weld-

1100

ing pressure the welded union resulting will be localized in the area of the opposed surfaces and will be substantially coextensive in area with the restricted area of the path of the effective heating current. Various ways of providing such points or projections will occur to those skilled in the art.

The preferred method is to indent the metal from the side reverse to that on which the union is effected by a suitable tool, the projections thus formed affording points for the passage of the electric current. This method is preferable also because it permits the welding to be produced at a multiplicity of spots simultaneously through the application of pressure over the whole rear surface of the plate, the points or projections in that case serving not only to localize the flow of the heating current but also to localize the welding pressure.

In the preferred manner of carrying out my invention in the case of sheet metal manufacture I provide projections from the meeting surfaces of both pieces that are to be united. Said projections may also be provided by interposing between the two plane sheets small pieces of conducting material which act in the same manner when the sheets are brought together, as projections which localize the heating current and the pressure. It will be understood, however, that in the latter instance as in the former, these pieces are so small and are placed such a distance apart that on the application of welding pressure there will be no running of the welds into one another but that the final union will be in spots only leaving well-defined areas on the meeting surfaces, in which the surfaces either lie in contact or separated from one another by a very thin space.

From the foregoing it will be seen that my invention is distinguished from prior methods of welding pieces of metal together in that it may be very cheaply practiced, because no attempt is made to weld over the whole of the opposed surfaces of the welded pieces; but on the contrary the union is at a spot or spots only which in ordinary cases will afford as strong a union as would be produced by the riveting of the pieces.

The invention further has the advantage that not nearly so much electric energy is required as is necessary when the electrically welded union extends over the whole area of the opposed surfaces. Moreover, the danger of burning when the attempt is made to weld two sheets of metal together by a lap weld is largely eliminated.

In the accompanying drawings Figures 1, 2, 3, 4 and 5 illustrate some of the ways in which the pieces of metal to be united may be prepared for the welding according to my invention. Figs. 6, 7, 8, and 9 show modifications in the form and disposition of the contact projections which result in the spots of electrically welded union. Fig. 10 shows the assembling of three plates together for welding according to my invention.

In the various figures of the drawing the invention is illustrated as carried out with two sheets of metal B. B'. In Fig. 1, plate B'. only is provided with the distinct or isolated spots (*c*) or projections for the flow of the electric current, to the plate B. which spots or points may be formed by indenting the plate with a suitable tool. The spots are located so far from one another that on the application of pressure coincidently with the flow of electric current from one plate to the other there will be a number of distinct areas or spots of electrically welded union of the plates separated by well-defined areas on the meeting surfaces in which no union takes place. The resultant is however a fastening of the plates together securely and which is practically as effective as if the attempt were made to form a welded union over the entire areas of the meeting surfaces. Obviously, the greater the distance between the spots the lesser the number that would be used and hence the lesser the consumption of energy in effecting the weld. This is of considerable importance where the meeting areas are large or where a considerable amount of work has to be done. The welding pressure is conveniently applied by conducting-blocks or electrodes, A, A', between which the two pieces B, B', are assembled. These electrodes, A, A', furnish the heating current while applying the pressure, the localization of the pressure in the spots being brought about in this instance by the pointing of the surfaces at point *c*.

In Fig. 2 both plates are provided with projections the points of which engage with one another, the pointing being produced by indenting the metal sheets from the rear.

Fig. 3 illustrates the localization of the welding by casting projections upon one of the sheets and Fig. 4 by casting projections on both pieces. The localization of the welding in spots might be effected as illustrated in Fig. 5 by interposing small pieces of metal at the spot or spots of desired union, these pieces operating when the plates are brought together in the same way as the projections before referred to. The number and size of the pieces and their distance apart is in this case, as before, so chosen that the application of pressure together with the flow of heating current from one plate to the other will result in a union of the two pieces over their opposed surfaces in spots only thereon.

Fig. 6 shows how the spots might be disposed to fasten the pieces together in distinct spots around their edges.

As shown in Figs. 7 and 8 the projections, instead of being round, might be somewhat elongated and irregularly or symmetrically arranged.

Fig. 9 shows round and somewhat elongated projections combined.

In all these instances however, the union over the surfaces of the plates is confined to spots or areas which are of comparatively small extent as compared with the total area of the meeting surfaces. As will be obvious, the form and disposition of the points or projections of initial contact for flow of the electric current and localization of the pressure may be greatly varied without departing from my invention.

Fig. 10 illustrates the welding of three plates of sheets together when superposed.

My invention is especially useful in the manufacture of articles from sheet metal which are stamped out to different forms, and which have heretofore had their component portions united by riveting or other purely mechanical expedient which is not only expensive but requires generally special tools and results in many cases in an insecure union. When the invention is employed in its preferred form or manner of practice in the field of sheet metal manufacture all that is necessary is to provide the contact spots or projections as already described and then to assemble the pieces in an electric welding machine and weld them together as already set forth.

The product of the foregoing process is readily distinguishable from that produced by melting down the metal of the pieces from the back at spots as proposed in the before mentioned patent of Bernardos in that there is no substantial alteration of condition of the metal back of the welds appearing as a burning, roughening or disintegration of the material by the very great heat of the electric arc employed for melting down the metal, and by the further fact that the unions themselves in the material of the juxtaposed or opposite faces have the characteristics of a true weld produced by bringing the metal to welding temperature only and applying pressure, so that the pieces are solidly and firmly united and cannot be readily torn apart as they could be if the metal at the spots has been melted down under the high temperature of the electric arc.

The product in the form of sheet metal is further particularly useful for sheet metal ware since the outer or exposed surface of the metal will have the smooth and practically unaltered finish of sheet metal and said surface will not be substantially marred when the process is properly conducted, excepting for the presence of such infrequent small depressions as might remain from the previous indentation of the metal from the back when, as hereinbefore described, an indenting of the metal may be resorted to.

The product in sheet metal also possesses the advantage that the spots of welding when located within the edges of the meeting surfaces will not show. The product is also superior to that produced by riveting of the plates in that there are no rivet heads to mar the finish of the back or outer surfaces of the metal.

What I claim as my invention is:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

7. The method of welding two pieces of metal together, consisting in superposing said pieces with their surfaces at which the union is to take place superposed or pre-

1102

sented to one another, pressing the pieces together, and passing a heating electric current from one to the other while localizing the heating current simultaneously in a number of distinct or separate spots of limited area, separated from one another sufficiently to secure a union of the pieces in a number of corresponding distinct spots surrounded by and separated from one another by distinct areas in which no union exists.

8. The method of uniting two pieces of metal, consisting in providing between their meeting surfaces a number of projections, spaced apart as described, pressing the pieces together and passing an electric current through said projections while confining the welding area of such current to said projections so as to leave distinct areas around spots in which no welding shall be produced.

9. The method of fastening two plates of metal together at a multiplicity of distinct or separate points of welded union, consisting in providing between them a number of isolated contact spots adapted to pass an electric current from one to the other but so separated that the electric welds will be separated from one another by unwelded areas, passing a heating electric current through such spots simultaneously and applying pressure as and for the purpose described.

10. The herein described method of electrically welding two plates or sheets of metal of any gage together by distinct spots of union disposed over their plane surfaces, consisting in providing a multiplicity of electrical contact spots coincident with the separated spots of union and disposed at such distances apart that there will be well-defined areas between spots through which the electric current will not flow, passing electric current from one plate to the other through said contact spots simultaneously and applying pressure as and for the purpose described.

11. The method of fastening two sheets of metal together, consisting in providing between them a number of isolated contact spots for the passage of the electric welding current, said spots being adapted to initially hold the plates apart and being separated from one another a sufficient distance to confine the welding to distinct areas or isolated spots, passing a heating electric current through a number of said contact spots simultaneously and pressing the plates together as and for the purpose described.

12. The method of fastening two plates of metal together, consisting in furnishing a surface of said plates with a number of projecting contact spots for the passage of welding electric current and disposed at such distances apart that on the application of pressure the welds will not run into one another, superposing said plates, passing a heating electric current from one to the other over said separated spots and applying the pressure to produce a spot-welding of the plates to one another as and for the purpose described.

13. The herein described method of fastening two pieces of metal together by providing each plate with a number of projecting contact spots on its plane surface disposed at such distances apart that the unions will not run into one another but will, nevertheless, firmly hold the plates together, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other through the spots and simultaneously applying pressure thus uniting the plates at a number of distinct points of welded union.

14. The method of uniting two sheets of metal face to face, consisting in indenting the material, superposing the plates with the points of the indentations engaged, passing an electric current from one plate to the other through said points simultaneously, and applying pressure while confining the area of heating to welding temperature to a circumscribed area or spot entirely surrounded by areas unheated to welding temperature to unite the pieces in a distinct spot or spots of small extent in the whole area of the opposed faces.

15. The herein described method of fastening two plates together at a multiplicity of distinct mechanically separated points of welded union, consisting in indenting each plate to form a number of projecting contact spots on the plane surfaces which are to abut, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other thereby forming a number of distinct zones or points of heated metal, heated to welding temperature, and applying pressure to complete the union of plates by a number of mechanically distinct unions.

16. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

20. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

DISCLAIMER.

928,701.—*Adolph F. Rietzel*, Lynn, Mass. UNITING THE COMPONENT PARTS OF COMPOSITE SHEET-METAL STRUCTURES. Patent dated July 20, 1909. Disclaimer filed June 12, 1915, by the assignee, *Thomson Electric Welding Company*.

Enters this disclaimer to that part of the invention described in said patent which is set forth in the specification in the following words:

"Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots"—except when that process is carried out by the preferred method of providing conducting projections or points between the meeting surfaces of the pieces to be united; and also enters its disclaimer to that part of the claim in the specification which is in the following words:

"1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

"2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

"3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

"4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

"5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

"6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

"16. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

"17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

"18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portions of the pieces back of the welds being substantially unaltered, as and for the purpose described.

"19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

"20. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points."—(*Official Gazette, June 22, 1915.*)

UNITED STATES PATENT OFFICE.

SEBASTIAN ZIANI DE FERRANTI, OF HAMPSTEAD, LONDON, ENGLAND.

PROCESS FOR ELECTRICALLY WELDING TURBINE-BLADES.

1,148,221. Specification of Letters Patent. Patented July 27, 1915.

Application filed May 14, 1904. Serial No. 208,034.

To all whom it may concern:

Be it known that I, SEBASTIAN ZIANI DE FERRANTI, a subject of the King of Great Britain and Ireland, and residing at 31 Lyndhurst road, Hampstead, London, N. W., England, have invented a certain new and useful Process for Electrically Welding Turbine-Blades, of which the following is a specification.

The invention relates to the electrical welding of turbine blades on to the wheels, rings or drums carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an inexpensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier, rapidly conducts heat away from the welding point thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of the blade carrying element in the neighborhood of the welding point so that approximately equal heating occurs in both faces to be welded.

Referring to the accompanying drawings which, with the exception of Figure 4, show the invention applied, by way of example, to a type of parallel flow turbine in which the blades are mounted on the edge of a wheel like body, Fig. 1 is a part side elevation of such a wheel having cross grooves, Fig. 1ª being an edge view; Fig. 2 shows a similar edge view of a modification in which sets of intersecting grooves are adopted; Fig. 3 shows an edge view of a form having circumferential grooves, Fig. 3ª being a section on the line A A of Fig. 3; Fig. 4 shows, in longitudinal sectional elevation, part of a drum carrier to which the blades are welded in accordance with one form of the invention; Figs. 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disk, while Fig. 7 is a part side elevation in which holes are bored through from face to face of the disk; Fig. 8 shows a sectional plan of a form of wheel built up of two dished disks, held apart at their circumferential portions by distance pieces, Fig. 8ª being a partial edge view to a larger scale; Fig. 9 is a similar sectional plan of a modified form of wheel built up of three disks, while Fig. 9ª is a corresponding partial edge view also to a larger scale; Fig. 10 shows a part sectional elevation of a wheel built up of two comparatively thick disks having notched edges, Fig. 10ª being a partial edge view, while Fig. 11 shows an edge view of a form of wheel built up of a series of "stepped" laminæ and Figs. 12 and 13 show a form of clamp and a diagram of the electrical connections.

(It will be seen that all the edge views in the preceding figures are shown as developments for clearness of drawing and not as true projections.)

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

In carrying out the invention according to the form shown in Figs. 1 and 1ª, the turbine wheel or disk is shown at *a*, cross grooves, *b*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded. The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disk, as is shown in Fig. 2, or by cutting circumferential grooves, such as *f*, completely around the edge (see Figs. 3 and 3ª.)

Fig. 4 shows the invention according to one form applied to the case of a drum blade carrier, *a'*; the drum is grooved circumferentially with grooves, *f'*, the intervening collars of metal being then cross-cut to form projecting teeth, *c'*, on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disk, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in Fig. 5, or arranged without particular reference to the position of the blades, (see Fig. 6).

In Fig. 7, a method is shown of removing

COPY BOUND CL

metal in the neighborhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disk at a radius slightly less than that of its outside edge. The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficient areas untouched to insure the mechanical strength in the welded joint.

Referring now to Figs. 8 and 8ª, a form of wheel is shown somewhat diagrammatically which is built up of two dished disks, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as *l*, disposed at a radius somewhat less than the maximum radius of the disks, the blades, *d*, being welded in position on their outside edges.

Figs. 9 and 9ª show a type of wheel generally similar to that last described but having an intermediate plane disk, *m*, in addition to the two dished disks, *k*; a portion, *n*, of the hub, *o*, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the disks in their correct relative position may be adopted.

In every case it will be seen that those portions of the carrier to which the blades are to be welded are partially isolated from the body of the carrier by slots, holes and so forth so as to limit the cross-sectional area available for the conduction of heat, and so compel the carrier to rise to the welding temperature. On the other hand to prevent the blades being burnt away, their mass is artificially increased by holding them between clamps or jaws of high heat conductive material such as copper. Thus referring to Figs. 12 and 13, the jaw holder 63, is separated into two branches by means of the slot, 64, each branch carrying a copper jaw, 65, shaped so as to clear adjacent blades. Between the jaws, 65, the blade to be welded is clamped, so as to leave the tip only exposed as seen in Fig. 13, and in order to insure a good contact and rigid holding of the blade in the jaws, a clamping device is preferably arranged in addition to that provided by the spring of the two branches of the jaw holder.

According to the form shown links, 66, are pivoted at 67, to one branch of the jaw holder, while short cross links, 68, connect the links, 66, to the other branch to which they are pivoted at 69. The long links, 66, are curved as shown, and are connected at their non-pivoted ends by the cross-piece, 70, to which pressure to clamp the blade is applied in the direction of the arrow (see Fig. 13) by means of the cam, 71, and the hand lever, 72, both of which are secured to a common axle rotatably mounted on any convenient support, 73. A spring such as 74, serves to return the links when the blade is released.

The necessary electrical connections to affect the welding are shown diagrammatically in Fig. 13, in which G represents an appropriate source of alternating current, and T, a transformer. It will be seen that while the lead, *t'*, may be connected directly to the carrier *a*, as in the example shown, it is necessary on the other hand that current to the blade, *d*, should be conveyed indirectly by way of the jaw holder, 63, and lead, t^2.

In Figs. 8 and 9, the dished disks, *k*, are indicated as secured to the hubs, *o*, by pressing the inner edges of these disks into grooves and subsequently burring over the hubs to hold the disks in place.

In the modification shown in Figs. 10 and 10ª, two dished disks, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to Figs. 1 and 1ª. Again, that portion of the disk carrying the blades may be built up of a set of thin laminæ, *r* (see Fig. 11) the edges of which are notched as at *s*, the laminæ being assembled in such a way that the notches, *s*, are "stepped" with regard to each other, so that the intervening projections of metal may follow the shape of the turbine blades to be welded to them.

Instead of notching the laminæ, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In an invention such as the present, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

The electric heating current is passed directly through the carrier and by way of clamps through the blades.

By means of my invention it will be seen that the blades are attached to their carrying elements in an expeditious and efficient manner while in the case of rotors a still further advantage is obtained over the methods of blading commonly employed inasmuch as if properly carried out the attachment of the blades by electric welding introduces no change of symmetry with respect to the axis of rotation and consequently dispenses with the tedious operation of balancing otherwise rendered necessary.

LOSE IN CENTER

Having now described my invention what I claim as new and desire to secure by Letters Patent is:—

1. The method of attaching turbine blades to their carrier of relatively great mass which consists in adjusting the heat capacity of the localized area of the carrier at the point of attachment by partially isolating these areas from the remainder of the carrier so that a welding temperature may be reached notwithstanding the cooling effect of the mass of the carrier, and passing a uniform electric heating current directly through the carrier and by way of the clamps through the blades to weld the blades in succession to the carrier, substantially as described.

2. The method of attaching turbine blades to their rotor carrying elements one by one, consisting in equalizing the heat capacity of the welding parts by limiting the conducting areas of the carrier at the points of blade attachment symmetrically in relation to the axis of rotation of the rotor, and inclosing the blades between clamps so that on heating locally by a uniform electric current, the blades and carrier rise to approximately the same temperature on welding the blades to the carrier so prepared, substantially as described.

3. Process for the attachment of turbine blades to their carriers consisting in partially isolating those portions of the carrier in the neighborhood of the points of attachment of the blades, to limit the cross-sectional area available for the conduction of heat therefrom; artifically increasing the volume of the blades by contacting them with metal masses of high heat conductive capacity and finally welding together the carriers and blades so prepared.

4. Process for the attachment of turbine blades to their carriers, consisting in forming circumferential grooves with intervening rings of metal around the carrier thereby limiting the cross sectional area available for the conduction of heat from the point of attachment so that on heating locally, said blade and said carrier rise to approximately the same temperature and welding each blade to a plurality of said rings, as set forth

5. The method herein described of constructing a turbine wheel, ring or drum, the same consisting first in forming said wheel symmetrically in relation to its center of rotation with the parts next to the welding points reduced to properly conform to the volume of the blades and electrically welding said blades at the said points whereby the symmetry of the wheel is maintained.

In witness whereof I have hereunto set my hand in presence of two witnesses.

UNITED STATES PATENT OFFICE.

To all to whom these presents shall come, Greeting:

THIS IS TO CERTIFY that the annexed is a true copy from the Records of this Office of the Complete Specification and Drawings, in the matter of the

British Letters Patent to

Charles Frederick Parkinson and Walter Gatwood,

Dated July 28, 1894, Number 14,536,

for

Improvements in Apparatus for Heating and Welding by Electricity.

IN TESTIMONY WHEREOF I have hereunto set my hand and caused the seal of the Patent Office to be affixed at the City of Washington, this 24th day of March in the year of our Lord one thousand nine hundred and nineteen, and of the Independence of the United States of America the one hundred and forty-third.

J. McClay

Acting Commissioner of Patents.

4-5m

In working, the secondary current induced in the core of the transformer is carried through the core to the base and then by the upright pillars or supports to the top plate and returned to the core when the circuit is completed through the part of the wheel or other article to be welded to the bottom plate which is electrically connected to the end of the core.

The V pieces which form the gluts are cut to the desired size and placed in position at the junction of the spokes while cold and the two (spokes and glut piece) are heated together to a welding heat and then compressed by the hydraulic rams.

Dated this 25th day of July 1894.

COMPLETE SPECIFICATION.

Improvements in Apparatus for Heating and Welding by Electricity.

We, CHARLES FREDERICK PARKINSON, of Wellington Terrace, Morecambe, in the County of Lancaster, Electrical Engineer, and WALTER GATWOOD, of Derwent Road, Lancaster, in the said County, Mechanical Engineer, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention is designed to provide an apparatus for welding metals by means of electric currents passed through the articles to raise them to welding heat.

It is primarily designed and arranged for glutting wheel spokes and bossing railway wagon and carriage wheel centres but the several parts may be arranged to suit other descriptions of work or to act upon articles of different shape.

The invention consists essentially in constructing the apparatus with one or more alternating or continuous current transformers or generators working in conjunction with a number of hydraulic cylinders and rams the transformers or generators being connected with the bed plate or support upon which the articles are placed so that the current passes through that part of the article or at the point which is required to be treated and maintains it at the desired temperature whilst the hydraulic rams compress it and effect the welding.

The invention will be fully described with reference to the accompanying drawings in which as an example a machine is shown for heating and welding railway carriage wheels.

Fig. 1. Elevation.

Fig. 2. Sectional elevation through two opposite cylinders, with rams removed showing section through transformer.

Fig. 3. Plan

Fig. 4. Longitudinal section of single cylinder.

Fig. 5. End elevation of same.

Fig. 6. Plan of parts of same.

In the apparatus illustrated for glutting wheels the number of hydraulic cylinders A and rams B and B¹ employed correspond with the number of spokes of the wheel C to be operated upon and these are arranged on a circular bed D radiating from a common centre.

At or near the centre of the apparatus in front of the hydraulic cylinder is placed an electrical transformer E preferably arranged for alternating currents. The secondary coil F of the transformer terminates with two star shaped poles G and H which also act as slides upon which sliding contact pieces or carriages I and J are capable of being moved to and fro. The top pole or star shaped piece of copper G carries the sliding pieces or carriages I and the bottom pole H the

upright sliding contact pieces J. The pieces J are preferably made in the form of or as part of a choking coil which when in use acts as a regulator to choke back the current and reduce the heating effect. A central pin K is provided to hold and support the wheel C whilst being heated and welded. It is fixed to but insulated from the secondary coil F of the transformer.

The contact pieces or carriages I connected to the top pole G carry the contact arms L which fit against the spokes of the wheel at the point to be heated. To the contact arms L may be fitted adjustable clamps L^1 to fit the radius of a larger wheel C^1 (a portion of which is shown in plan).

The upper end of the upright contact piece or carriage J connected to the lower pole H forms the slide for the contact block M which is caused to move to and fro therein by the forward or backward movement of the hydraulic ram B. Over and under the contact block M are placed die pieces b b^1 which are moved to and fro by the hollow hydraulic ram B^1.

The hydraulic cylinders A are arranged with a cast iron base or slide A^1 to which they are bolted. The slide or base A^1 is mounted on a circular bed plate D upon which they can be adjusted to any suitable position the number and position of the cylinders being regulated according to the number of spokes to be welded. The position of the cylinders can be adjusted circumferentially on the bed plate D and radially upon the slide or base A^1. The hand wheel S and screw s are arranged to move the cylinders to give the required adjustment on a radial line the screw being supported on a bracket a at the back of the base A^1.

Each cylinder A contains two rams, a solid one B and a hollow one B^1 the one sliding or working inside the other. Instead of two rams one working inside the other each cylinder may be constructed with two chambers separated by a division plate or diaphragm in which the ram works.

To the end of the ram B is fitted the sliding contact block M which moves to and fro in the slide formed by the upper end of the contact piece or carriage J and to the end of the hollow ram B^1 are fitted the die pieces b b^1 which move to and fro with it through recesses cut in the upper and lower sides of the contact block M.

Each sliding contact piece or carriage I is connected to the ram B of the corresponding hydraulic cylinder A by the connecting rod N and lever n which are pivoted together and to the fixed bracket N^1 the bracket N^1 being affixed to though insulated from the upright contact piece J.

The outward movement of the ram B carries forward the contact block M which makes contact with the glut piece C^{11} and holds it firmly against the outer rim of the wheel C at the same time bringing the contact arms L against the inner face of the wheel thereby completing the secondary circuit through the part of the wheel C and glut piece C^{11} to be heated. W W^1 are the primary leads.

Each of the upright contact pieces J is coupled to the corresponding cylinder by a connecting link R coupled to an eye bolt r in the face of the cylinder so that as the cylinder is moved back or forward to adjust its position to the size of wheel (or other work) the contact piece J is moved to or fro at the same time and by reason of the connecting rod N and lever n of the contact piece I being pivoted on the bracket N^1 its position is at the same time adjusted.

The water is admitted to the hydraulic cylinders A from the pipes T T^1 T^{11}. The pipe T admits to the back of the cylinder to move forward the ram B the pipe T^1 admits to the centre of the cylinder to propel forward the hollow ram B^1 and the pipe T^{11} admits to the front end of the cylinder to move both rams back again. Suitable valves are applied to these pipes and to the cylinder for controlling the flow of the water to the cylinder and the exhaust from it. The pipes T T^1 T^{11} each terminate in castings V V^1 V^{11} into which the small pipes t t^1 t^{11} slide being suitably packed so that when the position of the cylinders is altered they are free to slide with them. The upright part of the pipes T T^1 T^{11} may be of any suitable flexible piping to allow for the lateral movement of the cylinders.

N° 14,536.—A.D. 1894.

The secondary coil may be fitted with flexible pipe to allow of water circulating about it to keep the contacts cool.

Although one special form of machine is described and illustrated applicable for glutting railway carriage and wagon wheels it is to be understood that the construction of the apparatus may be varied to suit different forms of work.

In the construction of the machine several transformers may be employed placed diametrically opposite each other the secondary circuits of which are directly connected to the work in hand thus separate transformers can be applied to the different parts to be heated. When using more than one transformer we prefer to place in series with the primary current a choking coil or regulator.

The transformer or transformers are fixed beneath the wheel (or other work) with the secondary coil or coils terminating at the contacts I and J through the star shaped poles G and H. The wheel C (a portion of which is shown in Fig. 4) is placed upon the central supporting pin K.

The glut pieces C^{11} (which are forged to the width of the wheel to be welded) are then placed between the die pieces $b\ b^1$ as shown in Fig. 4 water is then admitted through the pipes T t to the back of the cylinders A and the rams B forced outwards by which movement the glut pieces C^{11} are carried forward by the contact blocks M and held against the spokes of the wheel at the same time the contact arms L (as shown in Figs. 2 and 3) are drawn against the inner face of wheel C thereby completing the secondary circuit through the metal.

The primary circuit of transformer is then closed and when the metal has been sufficiently heated the admission valve on pipe $T^1\ t^1$ is opened and water admitted into the centre of cylinder between the two rams this forces out the hollow ram B^1 which has fixed upon its end the two die pieces $b\ b^1$ (which slide through recesses in the contact block M) until they project over the glut piece and part of spokes heated forming a closed die around the weld the admission valve on pipe T^1 is then closed allowing the full pressure (available) on the contact block M fixed on the end of ram B thereby completing the weld.

Having now particularly described and ascertained the nature of the said invention and in what manner the same is to be performed we declare that what we claim is :—

1. An apparatus for heating and welding metals constructed with one or more electro transformers or generators the poles of which terminate in castings of star or other shape forming slides upon which carriages fitted with contacts move to and fro upon which the articles are placed so that the current passes through the article at the point desired to be heated in combination with a number of hydraulic cylinders and rams capable of being adjusted to the requisite position and of applying the desired amount of pressure to weld the metal whilst maintained at the desired temperature substantially as described.

2. In apparatus for heating and welding metals the combination with one or more transformers constructed with terminals in the form of slides in contact with the poles of the secondary circuit and a number of hydraulic cylinders and rams by which the contact pieces are brought into contact with the work and by which the necessary pressure is applied to make a weld substantially as described.

3. Apparatus for heating and welding metals constructed with the several parts arranged in combination substantially as described and shown.

COMPLETE SPECIFICATION.

"Improvements in and relating to the Electric Welding of Turbine Blades."

I, SEBASTIAN ZIANI DE FERRANTI, Engineer, of 31, Lyndhurst Road, Hampstead, London, N.W., do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:

The invention relates to improvements in and relating to methods of electrically welding turbine blades to the discs, drums or the like carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an inexpensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier rapidly conducts heat away from the welding point, thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of the blade carrying element in the neighbourhood of the welding point, so that approximately equal heating occurs in both faces to be welded.

Referring to the accompanying drawings which, with the exception of Figure 4, show the invention applied, by way of example, to a type of parallel flow turbine in which the blades are mounted on the edge of a wheel-like body.

Figure 1 is a part side elevation of such a wheel having cross grooves,

Figure 1ª being an edge view;

Figure 2 shows a similar edge view of a modification in which sets of intersecting grooves are adopted;

Figure 3 shows an edge view of a form having circumferential grooves,

Figure 3ª being a section on the line A A of Figure 3;

Figure 4 shows, in longitudinal sectional elevation, part of a drum carrier to which the blades are welded in accordance with one form of the invention;

Figures 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disc, while

Figure 7 is a part side elevation in which holes are bored through from face to face of the disc;

Figure 8 shows a sectional plan of a form of wheel built up of two dished discs, held apart at their circumferential portions by distance pieces.

1120

Figure 8ª being a scrap edge view to a larger scale;

Figure 9 is a similar sectional plan of a modified form of wheel built up of three discs, while

Figure 9ª is a corresponding scrap edge view also to a larger scale;

Figure 10 shows a part sectional elevation of a wheel built up of two comparatively thick discs having notched edges,

Figure 10ª being a scrap edge view, while finally

Figure 11 shows an edge view of a form of wheel built up of a series of "stepped" laminæ.

It will be seen that all the edge views are shown as developments for clearness of drawing and not as true projections.

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

In carrying out the invention according to the form shown in Figures 1 and 1ª, the turbine wheel or disc is shown at *a*, cross grooves, *b*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded.

The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disc, as is shown in Figure 2, or by cutting circumferential grooves, such as *f*, completely round the edge (see Figures 3 and 3ª.)

Figure 4 shows the invention, according to one form, applied to the case of a drum blade carrier, a^1; the drum is grooved circumferentially with grooves, f^1, the intervening collars of metal being then cross-cut to form projecting teeth, c^1, on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disc, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in Figure 5, or arranged without particular reference to the position of the blades, (see Figure 6).

In Figure 7, a method is shown of removing metal in the neighbourhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disc at a radius slightly less than that of its outside edge.

The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, whilst at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Referring now to Figures 8 and 8ª, a form of wheel is shown somewhat diagrammatically which is built up of two dished discs, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as *l*, disposed at a radius somewhat less than the maximum radius of the discs, the blades, *d*, being welded in position on their outside edges.

Figures 9 and 9ª show a type of wheel generally similar to that last described but having an intermediate plane disc, *m*, in addition to the two dished discs, *k*: a portion, *n*, of the hub, *o*, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the discs in their correct relative position may be adopted.

In Figures 8 and 9, the dished discs, *k*, are indicated as secured to the hubs, *o*, by pressing the inner edges of these discs into grooves and subsequently [illegible] over the hubs to hold the discs in place.

In the modification shown in Figures 10 and 10ª two dished discs, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to Figures 1 and 1ª.

Again, that portion of the disc carrying the blades, may be built up of a set of thin laminæ, *r*, (see Figure 11) the edges of which are notched as at *s*, the laminæ being assembled in such a way that the notches, *s*, are "stepped"

169464
22

with regard to each other, so that the intervening projections of metal may follow the shape of the turbine blades to be welded to them.

Instead of notching the laminae, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In an invention such as the present, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above, and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. In turbines, the method of welding the turbine blades to the element carrying them, consisting in so adjusting the volume of metal in the blade carrier in the neighbourhood of the welding point, that approximately equal heating occurs in the two parts, substantially as described.

2. In turbines, blade carrying elements having blades welded thereupon in accordance with the method claimed in Claim 1.

3. In turbines, grooving the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

4. The bladed turbine element, hereinbefore described with reference to Figures 1 and 1ª of the accompanying drawings.

5. The bladed turbine element, hereinbefore described with reference to Figure 2 of the accompanying drawings.

6. The bladed turbine element, hereinbefore described with reference to Figures 3 and 3ª of the accompanying drawings.

7. The bladed turbine element, hereinbefore described with reference to Figure 4 of the accompanying drawings.

8. In turbines, forming holes in the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

9. The bladed turbine elements hereinbefore described with reference to Figures 5 and 6 of the accompanying drawings.

10. The bladed turbine element, hereinbefore described with reference to Figure 7 of the accompanying drawings.

11. In turbines, building the blade carriers of comparatively thin parts across the non-touching edges of which the blades are welded, substantially as described.

12. The bladed turbine element, hereinbefore described with reference to Figures 8 and 8ª of the accompanying drawings.

13. The bladed turbine element, hereinbefore described with reference to Figures 9 and 9ª of the accompanying drawings.

14. The bladed turbine element, hereinbefore described with reference to Figures 10 and 10ª of the accompanying drawings.

15. In turbines, building the blade carriers of prepared laminae assembled in a "stepped" manner, substantially as and for the purpose hereinbefore described.

16. The bladed turbine element, hereinbefore described with reference to Figure 11 of the accompanying drawings.

Dated this 24th day of February, 1904.

OCT 1 1904
U.S. PATENT OFFICE

PROVISIONAL SPECIFICATION.

"Improvements in Welding by Electricity and Apparatus therefor".

I, JOHANN HARMATTA, of Kirchdrauf, in the Kingdom of Hungary, Engineer, do hereby declare the nature of this invention to be as follows:—

This invention relates to the production, by direct electric welding, of metal articles of all kinds, especially such as are made of thin sheet metal.

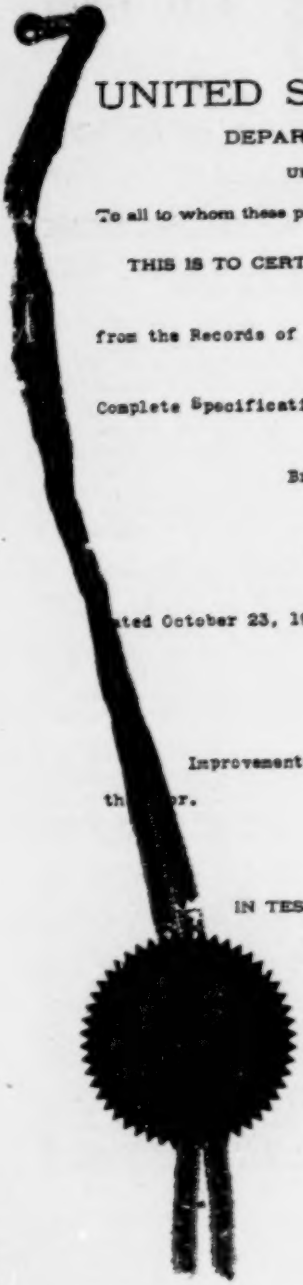
According to the invention one or both of the electrodes is or are not only utilized for supplying the electric current, but also for exerting pressure at the point at which the welding to be effected, before and during the supply of electric current or only during the time of flow. To this end the part which supplies the electricity serves simultaneously as the means for effecting the mechanical operation, this arrangement giving rise to the most favourable results as regards the operation, since, as is well known, in every efficient method of welding, the parts to be joined after being brought to the proper temperature must be immediately hammered or subjected to compression in order to obtain a good joint.

In no one of the known electric welding processes, are the parts to be welded, during the operation of welding, pressed against one another by means of one or both of the electrodes in order to assist the welding operation. Hitherto either no pressure at all has been made use of or pressure when used has been applied at some distance from the welding point or not upon centred electrodes pressing directly upon the parts to be heated. To sum up, in direct electric welding, pressure has never heretofore been applied by means of electrodes placed in the direction of flow of current directly over the surfaces or points to be welded.

The process forming the subject of this invention can be carried out in a number of ways, as the necessary pressure at the welding point can be obtained by any suitable known means for generating or transmitting pressure, for example, by means of a press, either directly or through the medium of lever transmission. Or, the pressure can be obtained by employing a hand lever by direct or indirect manual operation.

In carrying out the invention the metal parts (sheets or the like) the ends of which overlap are passed between the two electrodes, one of which is caused to exert pressure upon the parts to be welded either before the welding operation or during the said operation; or both the electrodes can be utilized for obtaining the required pressure. This may advantageously be done, particularly in cases where it is required to continuously weld longitudinal, transverse and circular joints, by providing in intimate contact with each of the conductors, a fork furnished with an easily exchangeable roller electrode; or only the lower of the two roller electrodes can be made exchangeable. Furthermore, only the upper or lower electrode need be in the form of a movable roller, the other electrode being the fixed contact conductor.

The roller of the upper conductor is keyed upon a spindle which carries a toothed pinion to which the motion of a suitably mounted hand wheel can be transmitted through the medium of a gear wheel; or the hand wheel can be directly mounted upon the spindle which it can thus drive without intermediate



[*Price 8d.*]

gear. Furthermore, the spindle can have mounted upon its other end a pinion, bevel wheel driving disc or the like for mechanically driving the roller electrode where the automatic feeding of the parts to be welded by motive power is desired. The hand wheel is designed to increase or retard the rotation of the roller according to requirement, or to operate the said roller directly by hand. The retardation or acceleration of the motion of the spindle with a power drive can obviously be effected by other suitable means. The upper part of the forked piece carrying the roller electrode can be in the form of a rack with which engages a pinion carried by the conductor through the medium of a clamp, the said pinion being keyed upon a spindle which at its other end is provided with a hand lever. By raising or lowering the said hand lever the upper roller electrode can obviously be moved from, or approached towards, the lower electrode. Furthermore, by raising or lowering the forked piece of the lower conductor the lower exchangeable roller can be adjusted in position.

If, now, the materials to be welded be introduced between the two roller electrodes and current caused to flow, a continuous welding can be obtained, that is to say, an unbroken joint can be made, the upper rotating roller electrode pressing upon the lower fixed or rotatable roller electrode so that the two ends of the work to be welded are rigidly connected together.

Instead of gradually feeding the parts to be welded between the electrodes the electrical welding apparatus can be made to move relatively with the work, in this case fixed in position.

In cases where it is desired to weld metal sheets at single points only I advantageously make use of apparatus wherein the electrodes are in the form of rods or pins. The lower electrode is fitted in the lower conductor, whilst the upper electrode is carried by a yoke adapted to be turned around a spindle or axis by a hand lever in such a manner that the points of the electrodes can be approached towards, or moved away from, one another. If now, for example, two overlapping sheet metal ends to be welded are introduced between the electrodes, and the latter pressed towards one another and current allowed to flow, then a small, round and clean welding point is obtained which fully takes the place of a rivet. The pressure at the welding point at suitable intervals can be exactly regulated, that is to say, kept within proper limits, particularly in the case of welding thin vessels which cannot sustain any considerable pressure.

Dated the 20th day of October 1903.

COMPLETE SPECIFICATION.

"Improvements in Welding by Electricity and Apparatus therefor"

I, JOHANN HARMATTA, of Kirchdrauf, in the Kingdom of Hungary, Engineer, do hereby declare the nature of this invention and in what manner the same is to be performed to be particularly described and ascertained in and by the following statement:—

This invention relates to a method of electrically welding thin metal sheets of a thickness of about two millimeters.

It is well known that it is not possible, with electric welding processes

heretofore in vogue, to make a sound welding joint between sheets of such small thickness as above mentioned that is to say, a joint which is completely tight throughout, without igniting and burning the material to be welded.

The inventor has found that this is due to the following facts. In the known methods of welding it is usual to convey current to the articles to be welded (for example, iron rods, tyres, chains, links or the like) whereby the layer of air of more or less thickness, which is always present between the two objects to be welded, gives rise to an energetic formation of sparks, that is to say, a sparking area or an arc, this continuing until the bodies to be welded are brought to the welding heat by the current, when they are pressed together for effecting their union.

This known method of welding does not differ essentially from the ordinary welding by fire heat, except that the bodies to be welded are heated by the electric current instead of by the gases of combustion derived from a suitable combustible material; as soon as the necessary temperature is attained, however, the final jointing of the bodies is in both cases effected by mechanical pressure, such as pressing or hammering.

In the diagrammatic view shewn in Figure 1 of the accompanying drawing, and in which it is assumed that two sheets 1 and 2 are to be welded by the ordinary method of electric welding, two electrodes *a* and *b* are placed opposite one another. The two metal sheets 1 and 2 are placed between the two electrodes and lie loosely upon one another (that is to say, they are not mechanically or otherwise pressed together) and are consequently separated by a layer of air 3. If, now, the circuit containing the electrodes *a* and *b* and the two sheets be closed and the air layer 3 is of sufficient thickness, that is to say, the resistance of the air sufficiently great, no sparks or arcs are initially formed between the sheets. When, however, the sheets are approached towards one another, which is unavoidable for the final welding by pressure, hammering, *etc.*, as above mentioned, then a point is reached at which the air resistance between the two sheets to be welded is no longer sufficiently great to prevent the passage of electricity, whereby arcing or sparking takes place between the sheets and continues until an intimate contact between the two sheets takes place. When relatively thick sheets (as is shewn in Figure 1) are treated in this manner the formation of the arcs is not injurious, since the small fusions 4, which are occasioned by the arcs or sparks, are not of sufficient depth to perforate or break through the thickness of the material. On the contrary an advantage is obtained as the sparks or arcs effect an alteration in the cross sectional area of the material thinning the same at the joint, that is to say, reducing the total cross sectional areas at the joint to an extent such that, in certain circumstances, the resulting total thickness is equal to that of one of the sheets.

The conditions, however are quite different when welding thin bodies, or a thin body and a thicker body as is diagrammatically indicated in Figure 2 of the accompanying drawing. In this figure, it is assumed that the thicker sheet 2 which under the conditions given in Figure 1 is not perforated by the fusion shewn at 4, is to be electrically welded to a thin sheet 5. In carrying out the process, when the two sheets 2 and 5 are approached towards one another at the required moment, as above described, the sparking through the air layer 3 causes the fusion of the metal sheets, the fusion taking place to a depth which is of no consequence in the sheet 2, but which in the case of the sheet 5 is sufficient to completely perforate and burn it. The usual method of welding, therefore, is not practicable in the case of such thin sheets as that illustrated at 5, Figure 2, that is to say, a sheet of a thickness of 2 millimeters and under.

The novel method of electric welding forming the subject of this invention is characterised chiefly by the fact that it prevents the formation of such injurious arcing or sparking during the welding of thin bodies, thereby enabling

such bodies to be connected together by a perfectly sound weld, and also permitting of the sound welding of a thin body and a thicker body.

To prevent the formation of the injurious arcing or sparking according to this invention, I exert upon the superposed metal plates 4 and 5 (Figures 4 and 5) a pressure which varies in accordance with the articles to be welded, this pressure being exerted by the electrodes *a*, *b*, and being supplemented, *if desired* by that obtained by other means hereafter to be described. This pressure has for its object to bring the metal parts to be joined into such intimate contact that the layer of air existing between them is destroyed as far as possible. The two parts to be welded are by this means formed so as to say to a single body mechanically. This is of particular importance when two very thin sheets are to be welded together, for, as is well known, thin sheets always possess a more or less wavy form, and cannot be manufactured with as level surfaces as is the case with thicker sheets. Such sheets, therefore, when they are superposed without mechanical pressure do not lie closely upon one another, but by reason of their irregular wavy shape form a number of air spaces (Figure 3), which, when an electric current is passed through them, are very favorable to the formation of sparks and arcs.

After the metal articles to be welded are treated in the manner above described, that is to say, tightly pressed together by mechanical pressure so as to prevent the existence of air air layer between them, the electric circuit is closed, whilst the surface pressure is maintained.

At those points at which the electrodes *a*, *b* exert their pressure (Figures 4 and 5), that is to say, at which the current can flow through the two bodies to be welded without having to perforate an air layer and form sparks, the metal is heated up to the welding heat. As soon as this heat is obtained, the continuous pressure effects the desired union, that is to say, the welding of the two metal bodies 5 and 6, without the occurrence of damage arising from the perforation, burning, *etc.* of the bodies, even should these be composed of very thin material. It is furthermore to be noted that the pressure which is exerted upon the bodies to be welded, both anterior to, and during, the welding operation, and which pressure can be regulated to suit the character of the metal bodies, is adjusted in accordance with the actual thickness of the sheets. Thicker sheets or bodies do not require so great a pressure as thinner sheets, since, as above mentioned, they possess a more even regular surface, and when superposed can easily be closed so as to prevent the existence of injurious air layers. As the essential requirement is that the metal bodies to be united shall be tightly pressed together before welding, in order to prevent the perforation of the thin body by the electric current, it will be clear that the process is applicable not only to sheets of equal thicknesses, but also to the welding of a thin sheet and a thicker metal article without the liability of the burning of the former.

It will be obvious that the pressure can be exerted either by one of the electrodes only or by both the electrodes.

For carrying out the process when it is applied to the continuous welding of longitudinal, transverse and edge joints, the device illustrated in Figures 6 and 7 of the accompanying drawing can be used. Figure 6 indicates a front view of the device, and Figure 7 a sectional side view thereof.

Between the two current conductors *c*, *d* (Fig. 7) and in intimate contact therewith, are arranged forks *e*, *f*, each of which is furnished with an easily exchangeable roller-electrode *g* or *h*; or only the lower of the two electrodes may be made exchangeable. Furthermore, only the lower or the upper electrode need be in the form of a movable roller, the other electrode being the fixed current conductor. The roller *g* of the upper conductor *c* is keyed upon a spindle *i*, which carries a toothed pinion, to which the motion of a suitably mounted hand-wheel *l* can be transmitted through the medium of a gear wheel *m*, or the hand-wheel can be directly mounted upon

the spindle, that is to say, can be directly driven from the spindle *i*. Furthermore the spindle *i* can have mounted upon its other end a pinion, bevel wheel, driving disc or the like for mechanically driving the roller-electrode where the automatic feeding of the parts to be welded by motive power is desired. The hand-wheel is designed to increase or retard the rotation of the roller *g* according to requirement, or to operate the said roller directly by hand. The retardation or acceleration of the motion of the spindle *i* with a power drive can obviously be effected by other suitable means. The upper part of the fork carrying the roller-electrode *g* can be in the form of a rack *n* as shown, the said rack engaging a pinion *p* carried by the conductor *e* through the medium of a clamp *o*, and keyed upon a spindle *q* having a hand lever *r*. By raising or lowering the hand lever *r* the upper roller-electrode *g* can be moved from, or approached towards, the lower electrode *h*. Furthermore, by raising or lowering the fork *f* in the conductor *d* the lower exchangeable roller *h* can be adjusted in position.

If, now, the materials to be welded be introduced between the two roller electrodes and current caused to flow, whilst the pressure is maintained, a continuous welding can be obtained, that is to say, an unbroken sound joint can be made, even in the case of thin sheets.

Instead of gradually feeding the parts to be welded between the electrodes the electrical welding apparatus can be made to move relatively with the work, in this case fixed in position.

In cases where it is desired to weld metal sheets at single points only I advantageously make use of apparatus wherein the electrodes are in the form of rods or pins. Such an arrangement is shown in side elevation in Figure 8. *a* and *b* represent the pin electrodes, the lower *b* being fitted in the conductor *d* whilst the upper *a* is carried by a yoke *s* adapted to be turned around a spindle or axis *u* by a hand-lever *t* in such a manner that the points of the electrodes can be approached towards, or moved away from, one another. If now, for example, two overlapping sheet metal ends to be welded be introduced between the electrodes *a*, *b*, and the latter pressed towards one another and current allowed to flow, then a small, round and clean welding point is obtained which fully takes the place of a rivet. The pressure at the welding point at suitable intervals can be exactly regulated, that is to say, kept within proper limits, particularly in the case of welding thin vessels which cannot sustain any considerable pressure.

Having now particularly described and ascertained the nature of the said invention, and in what manner the same is to be performed, I declare that what I claim is:—

1. A method of electrically welding thin metal sheets or thin and thick sheets or bodies, wherein the said sheets are superposed and subjected to pressure at the point to be welded, the pressure being maintained during the subsequent heating of the sheets or bodies by an electric current, substantially as and for the purpose hereinbefore described.

2. In electrically welding thin sheets and bodies, the arrangement wherein pressure is exerted upon the bodies at the points to be welded both before and during the passage of the electric current by means of oppositely placed pin electrodes controlled by a lever or the like, substantially as hereinbefore described.

3. In electrically welding thin sheets and bodies, the arrangement wherein pressure is exerted upon the bodies, both before and during the passage of the electric current, by oppositely placed electrodes, one of which is in the form of a movable roller and the other of a fixed current conductor adapted to receive the bodies to be welded, or both of which are in the form of roller-electrodes, one or both of which is or are actuated to effect the automatic feed

of the work whilst maintaining the necessary pressure, substantially as herein-before described.

4. Apparatus for electrically welding thin bodies or thin and thick bodies constructed substantially as hereinbefore described and illustrated in the accompanying drawings.

N° 335.889

Brevet de quinze ans demandé le 13 octobre 1903, par **M. Wilhelm EGEL** résidant en Allemagne.

Procédé et dispositif pour la fabrication d'objets métalliques de tous genres, principalement d'objets composés de parties minces, d'épaisseurs différentes, par soudage électrique direct.

Délivré le 21 décembre 1903; publié le 18 février 1904.

La présente invention a pour objet un procédé pour la fabrication d'objets métalliques de tous genres, particulièrement aussi de ceux qui se composent de parties d'épaisseurs différentes, par soudage électrique direct. Le nouveau procédé consiste en ce que l'électrode qui s'applique contre le corps métallique qui a la plus grande épaisseur est soumise pour une tension relativement faible à une quantité de courant plus grande par unité de temps que l'électrode qui s'applique contre le corps métallique (fer-blanc, etc.) d'une épaisseur moindre. Un calcul toujours exact des proportions de courant évite que le corps métallique le plus mince ne soit brûlé, c'est-à-dire détérioré.

On peut exécuter le procédé de différentes façons; cependant, on donne la préférence à un dispositif qui convient particulièrement pour le but. Ce dispositif est caractérisé en principe en ce qu'un des deux conducteurs appartenant au circuit secondaire d'un transformateur possède une section de passage réglable, afin de pouvoir amener, à l'un ou à l'autre des corps métalliques qu'il s'agit de souder, les différentes quantités de courant, selon les besoins actuels du travail.

Au dessin, la fig. 1 montre que pour le soudage de tôles, etc., d'épaisseurs différentes les deux électrodes sont alimentées par des courants d'intensités différentes et cette manière de disposer des électrodes a surtout pour but de remplacer sur les objets traités certaines rivures par des soudures électriques.

La fig. 2 est une vue schématique d'un dispositif qui peut être employé avantageusement pour l'exécution du procédé, surtout lorsqu'il s'agit d'un soudage progressif continu de sutures longitudinales, transversales et circulaires, pour des récipients en fer-blanc et objets métalliques de tous genres.

Les fig. 3 et 4 représentent en élévation de face et en élévation de côté une exécution pratique des conducteurs qui amènent le courant aux électrodes.

Bien que pour des sections métalliques différentes plus grandes, la circonstance que, dans les machines à souder existantes, les deux pôles ne fournissent que la même quantité d'électricité de la même tension, ne soit pas aussi grave, le cas est tout à fait différent lorsqu'il s'agit de souder des objets de la matière la plus mince avec d'autres d'une épaisseur considérablement supérieure, comme cela a lieu, par exemple, lorsqu'il s'agit de souder du fil métallique ou de la tôle, avant,

par exemple, 4 millimètres d'épaisseur, sur du fer-blanc n'ayant que 0,3 millimètres d'épaisseur. Si on amenait des quantités de courant égales, le fer-blanc de 0,3 millimètres serait brûlé depuis longtemps, avant que le fil métallique de 4 millimètres soit seulement devenu rouge.

Suivant le présent procédé, on supprime cet inconvénient en amenant, à une tension égale des quantités de courants différentes par unité de temps, par exemple, comme le montre la fig. 1, pour une électrode *a* 1.000 et pour l'autre *b* 3.000 ampères, avec une tension de 0,3 - 4 volts. Il serait possible d'employer dans ce but deux circuits qui amèneraient aux endroits voulus une quantité différente d'ampères. Pour les applications pratiques cependant il convient d'employer un seul circuit et des essais en ce sens ont démontré que pour cela le circuit secondaire d'un transformateur qui réduit la tension à une faible quantité de volts, convient spécialement.

A la fig. 2, *c* désigne l'enroulement primaire et *d* l'enroulement secondaire d'un transformateur.

L'un des conducteurs, *e f* (ou bien les deux) ne constitue pas, en un certain endroit, une pièce pleine, mais est interrompu en cet endroit, et entre les deux extrémités du conducteur sont intercalées des lamelles métalliques parallèles *g*, de préférence en cuivre, dont la section totale est exactement égale à la section du conducteur proprement dit. On peut, selon les exigences actuelles du travail, enlever un nombre plus ou moins grand de ces lamelles pour réduire ainsi la section du conducteur, c'est-à-dire pour déterminer le passage d'une quantité d'électricité, par unité de temps, exactement fixée d'avance. Comme de cette façon on réduit, selon les besoins, l'arrivée de courant à l'une ou à l'autre des électrodes, on peut amener en même temps au blanc-soudant les deux sections qu'il s'agit de souder l'une à l'autre. Par conséquent la possibilité de brûler le corps métallique le plus mince disparaît complètement; et pour prouver qu'un réglage de l'arrivée du courant est possible dans les limites les plus larges, on peut à titre démonstratif réussir à brûler d'abord la section la plus forte en cherchant à souder deux sections d'épaisseurs différentes.

Les essais faits ont démontré que des courants d'une si faible tension et d'une intensité relativement grande, sont très inertes, de sorte que l'équilibre de courant au point de soudure ne se produit pas tout de suite, de sorte qu'il est possible qu'il se produise une retenue de courant dans un des conducteurs.

Pour des applications pratiques on peut disposer l'arrangement pour régler le courant de la manière indiquée aux fig. 3 et 4.

La source de courant est reliée à deux supports *i* ayant une forme et une longueur correspondantes et dans ces supports sont disposés deux bons conducteurs électriques *e f* d'aussi peu de résistance que possible. Dans la forme d'exécution représentée aux fig. 3 et 4 le conducteur supérieur seul est muni d'un dispositif régulateur de courant. A cet effet, il est muni d'une rainure dans laquelle sont placées les extrémités de diverses barres *g* ou de lamelles, câbles, etc., de conductibilité également bonne, et convenables, ayant une section appropriée et présentant peu de résistance au passage du courant. L'autre extrémité de ces barres, plaques, etc., se trouve en contact intime dans une rainure de la même forme pratiquée dans l'extrémité de la source de courant *i*. Les extrémités des conducteurs *e f* qui sont éloignées de la source de courant, sont munies des électrodes *a b* qui de préférence ont la forme de galets; l'une des électrodes peut être pressée au moyen d'un levier ou autre dispositif analogue, vers l'autre, ou bien les deux électrodes peuvent être pressées également l'une vers l'autre.

Lorsque l'admission du courant aux deux électrodes doit être changée, on enlève, selon le besoin, un nombre plus ou moins grand des barres, plaques ou lamelles *g* du conducteur qui est destiné à fournir le courant plus faible (dans le cas représenté le conducteur supérieur) de façon à augmenter sa résistance, de sorte qu'une quantité moindre de courant passe par le conducteur respectif à l'électrode.

Naturellement on peut aussi produire le réglage de la quantité de courant, aux endroits de la soudure qui exigent moins de courant, au moyen d'autres dispositifs quelconques qui réduisent ou augmentent le passage du courant.

L'opération, lorsqu'il s'agit de souder des

corps métalliques d'épaisseurs différentes, est la suivante :

On dispose les parties en tôle, ou autres qu'il s'agit de souder les unes au-dessus ou à côté des autres, après quoi on serre les électrodes (à galet ou autres) et on ferme le circuit primaire. Le courant secondaire formé par suite de cette fermeture du circuit par le transformateur passe par le conducteur à section variable aux électrodes et de là dans la matière qu'il s'agit de souder, et ce circuit secondaire est achevé par la section qu'il s'agit de souder, c'est-à-dire au point de soudure.

RÉSUMÉ :

1° Un procédé pour fabriquer des objets métalliques de tous genres, et particulièrement des objets composés de parties relativement minces, d'épaisseurs différentes, par soudage électrique direct, caractérisé en ce qu'à l'électrode qui s'applique contre le corps métallique de section plus grande (fer-blanc, etc.), on amène, avec la même tension, une quantité de courant plus grande par unité de temps qu'à l'électrode appliquée contre le corps métallique fer-blanc ou autre de section moindre.

2° L'admission du courant aux électrodes a lieu au moyen de deux conducteurs appartenant au circuit secondaire d'un transformateur et possédant une résistance faible, et dont l'un, ou éventuellement les deux, ont une section réglable suivant les besoins, afin de pouvoir amener des quantités de courants différentes à l'un ou à l'autre des corps métalliques qu'il s'agit de souder et qui ont des sections différentes.

3° Dans le circuit de l'un des conducteurs sont intercalées des lamelles métalliques, de préférence en cuivre, facilement détachables et portées par des sabots convenables et dont le nombre, variable suivant les besoins du travail, détermine la quantité de courant passant par unité de temps.

FRENCH PATENT No. 335,889—WILHELM EGEL—*October* 13, 1903

Process and Means for the Manufacture of Metal Objects of All Kinds, Principally Objects Composed of Thin Parts, of Different Thicknesses, by Direct Electric Welding.

(DELIVERED DECEMBER 21, 1903; PUBLISHED FEBRUARY 18, 1904)

The present invention has for its object a process for the manufacture of metallic objects of all kinds, particularly those which comprise parts of different thicknesses, by direct electric welding. The new process consists in that the electrode, which is applied against the metallic body which has the greatest thickness, is subjected, for a relatively weak potential, to a greater quantity of current per unit of time than the electrode, which is applied against the metallic body (tin, etc.) of less thickness. An always exact calculation of the proportions of current prevents the thinner metallic body from being burned, that is to say, deteriorated.

The process may be carried out in different ways; however, preference is given to a means which is particularly suited for the object in view. This means is characterized, in principle, by the fact that one of the two conductors, belonging to the secondary circuit of a transformer, possesses a section of variable size, in order to be able to feed, to one or the other of the metallic bodies to be welded, the different quantities of current, according to the actual needs of the work.

In the drawing, Fig. 1 shows that for the welding of sheets, etc., of different thicknesses, the two electrodes are fed by currents of different intensities, and this manner of arranging the electrodes has especially for its object to substitute electric welds for rivets in the objects treated.

Fig. 2 is a diagrammatic view of a means which may be employed advantageously to carry out the process, especially when it relates to a progressive continuous welding of longitudinal, transverse and circular seams, for tin vessels and metallic objects of all kinds.

Figs. 3 and 4 represent in front elevation and in side elevation a practical embodiment of the conductors which feed the current to the electrodes.

Although for larger different metallic sections, the circumstances that, in existing welding machines, the two poles only furnish the same quantity of electricity at the same potential, is not of so much importance, the case is entirely different when it relates to welding objects of very thin material to others of a considerably greater thickness, as is the case, for example, when a metallic wire or sheet of, for instance, 4 millimeters thickness, is to be welded to sheet tin having only 0.3 millimeters of thickness. If equal quantities of current were fed, the sheet tin of 0.3 mms. would be burned

long before the metallic wire of 4 mms. was even heated to red heat.

According to the present process this difficulty is overcome by feeding, at equal potential, different quantities of current per unit of time, for example, as shown in Fig. 1, for one electrode a, 1,000 amperes, and for the other b, 3,000 amperes, with a potential of 0.5-4 volts. It would be possible to use for this purpose two circuits which would feed at the desired points a different quantity of amperes. For practical applications, however, it is sufficient to employ a single circuit, and experiments along this line have demonstrated that, for that, the secondary circuit of a transformer, which reduces the potential to a small quantity of volts, is particularly suitable.

In Fig. 2, *c* indicates the primary winding and *d* the secondary winding of a transformer.

One of the conductors *e f* (or else both of them) does not constitute, at a certain place, a solid piece, but is interrupted at that place, and between the two ends of the conductor are interposed parallel metallic plates *g*, preferably of copper, the total section of which is exactly equal to the section of the conductor proper. According to the actual exigencies of the work, a greater or less number of these plates may be removed, to thus reduce the section of the conductor, that is to say to permit the passage of a quantity of electricity, per unit of time, exactly determined in advance, as in this way, the arrival of current at one or the other of the electrodes is reduced, as needed, sections which are to be welded can be brought at the same time to white heat the two. In consequence, the possibility of burning the thinner metallic body disappears completely, and to prove that a regulation of the arrival of the current is possible within the widest limits, it is possible, by way of experiment, to burn first the thicker section in trying to weld two sections of different thicknesses.

The experiments made have shown that currents of such a low potential and of a relatively high intensity, are very inert, so that the equilibrium of the current at the point of the weld is not produced at once, whereby it is possible that there is produced a retention of the current in one of the conductors.

For practical applications the means for regulating the current may be arranged as shown in Figs. 3 and 4.

The source of current is connected to two supports *i*, having corresponding shape and length, and in these supports are placed two good electric conductors *e*, *f*, of as little resistance as possible. In the embodiment represented in Figs. 3 and 4, the upper conductor *e* only is provided with a current regulator. To this end, it is provided with a groove, in which are placed the end of several bars *g*, or little blades, cables, etc., of equally good conductivity, having an appropriate section and presenting little resistance to the passage of the current. The other end of these bars, plates, etc., is in intimate contact in a groove of the same shape formed in the end of the source of current *i*. The ends of the conductors *e*, *f*, which are

furthest from the source of current, are provided with the electrodes, *a*, *b*, which preferably are in the form of rollers; one of these electrodes may be pressed, by means of a lever or other similar device, towards the other, or else the two electrodes may be equally pressed the one towards the other.

When the admission of the current to the two electrodes is to be changed, there is removed, as needed, a greater or less number of the bars, plates, or blades *g* of the conductor which supplies the weaker current, (in the case represented, the upper conductor), so as to increase its resistance, whereby a less quantity of current passes through the respective conductor to the electrode.

Naturally, the regulation of the amount of current can also take place at the places of welding which require less current, by means of any other devices which reduce or increase the flow of the current. The operation, when it has to do with welding metal objects of different thicknesses, is as follows:

The sheet metal, or other pieces, to be welded, are placed one above or at the side of the other, after which the electrodes (rollers or not) are applied and the primary circuit is closed. The secondary current generated in consequence of this closing of the primary, passes through the conductor of variable section to the electrodes, and, from there, into the material which is to be welded, and this secondary circuit is completed by the section which is to be welded, that is to say, at the point of weld.

CLAIMS.

1. A process for manufacturing metallic objects of all kinds, and particularly objects composed of relatively thin parts, of different thicknesses, by direct electric welding, characterized by the fact that, to the electrode which is applied against the metal body of greater section, (tin, etc.), there is supplied, at the same potential an amount of current greater per unit of time than to the electrode applied against the metal body, (tin or the like), of less section.

2. The admission of current to the electrodes takes place by means of two conductors belonging to the secondary circuit of a transformer and possessing a feeble resistance, and one of which, or in some cases both, has or have a variable section according to the requirements, in order to be able to feed different quantities of current to the one or the other of the metal bodies to be welded and which have different sections.

3. In the circuit of the one of the conductors are interposed some metallic blades, preferably of copper, easily detachable and carried by suitable shoes, and the number of which, variable according to the needs of the work, determines the quantity of current flowing per unit of time.

LIBRARY
PATENT OFFICE

Brevet de quinze ans demandé le 13 octobre 1903, par **M. Wilhelm EGEL** résidant en Allemagne.

Procédé et dispositif pour la fabrication d'objets métalliques de tous genres, principalement des objets en feuilles extrêmement minces par soudage électrique direct.

Délivré le 7 janvier 1904; publié le 1er mars 1904.

La présente invention a pour objet un procédé pour la fabrication d'objets métalliques de tous genres, principalement d'objets en feuilles extrêmement minces, par soudage électrique direct. Le nouveau procédé consiste en ce que l'une des électrodes ou même les deux ne servent pas seulement à amener le courant électrique, mais sont utilisées également pour exercer avant et pendant l'admission du courant électrique, ou bien seulement au moment de cette admission, une pression plus ou moins forte sur le point où doit avoir lieu le soudage. Par conséquent le corps qui conduit l'électricité constitue en même temps l'organe mécanique, de sorte qu'on obtient les conditions de travail de beaucoup les plus favorables, parce que dans chaque procédé de soudage régulier il faut immédiatement, ainsi qu'il est connu, marteler énergiquement ou comprimer le point de soudure amené à la température voulue, pour obtenir une soudure irréprochable.

Or, dans aucun des procédés de soudage électrique connus les corps qu'il s'agit de souder ne sont pendant le soudage pressés solidement l'un sur l'autre par une des électrodes ou par les deux pour favoriser le soudage. Jusqu'à présent on n'exerçait aucune action de compression, ou bien elle avait lieu à une certaine distance du point où s'effectuait le soudage, mais non au moyen d'électrodes centrées, comprimant directement le point qu'il s'agit de chauffer. En un mot, jusqu'à présent on n'a jamais exercé une pression lors du soudage électrique, au moyen d'électrodes, disposées dans la direction du courant, immédiatement au-dessus de la surface de soudure ou du point de soudure.

Pour exécuter ce procédé on peut se servir de différents dispositifs parce que la pression nécessaire sur le point de soudure peut être effectuée au moyen de tous les dispositifs auxiliaires techniques, capables de produire ou de transmettre une pression, par exemple au moyen d'une presse, directement ou par transmission par levier. Cependant ce travail peut être effectué aussi simplement au moyen de leviers à main ou par l'action humaine directe ou indirecte.

Au dessin :

La fig. 1 représente le soudage, effectué suivant le présent procédé, de deux feuilles de même épaisseur, d'une manière intermittente ou par endroits.

La fig. 2 est une élévation de face.

La fig. 3 est une élévation de côté d'un

dispositif de soudage électrique à fonctionnement continu dans lequel l'action de pression est exercée par des électrodes à galet, de sorte que successivement les divers points du joint qu'il s'agit de souder sont réunis avec une consommation minima de courant.

La fig. 4 représente le soudage du joint longitudinal d'un corps creux cylindrique ou conique suivant le nouveau procédé.

La fig. 5 est une élévation de côté d'un dispositif de soudage déjà indiqué à la fig. 1 et dans lequel on se sert, pour exercer la pression, d'électrodes en forme de tenons façonnés, suivant les besoins, et qui peuvent être préparés pour des surfaces de contact aussi restreintes que possible.

La fig. 6 représente deux formes pratiques d'électrodes qui se touchent à leurs extrémités.

Ainsi que le montre la fig. 1, on introduit les deux corps métalliques (fer-blanc ou autre) dont les extrémités se recouvrent, entre les deux électrodes *a b*. De ces électrodes l'une est déjà appliquée légèrement avant le soudage, ou seulement pendant le soudage, ainsi qu'il est indiqué par une flèche, sur l'autre électrode, ou bien les deux électrodes peuvent exercer ensemble une action de pression sur les objets qu'il s'agit de souder.

Pour l'exécution du procédé on peut, lorsqu'il s'agit d'une action continue du soudage pour des jonctions longitudinales, transversales et en rond, employer avantageusement le dispositif représenté aux fig. 2 et 3 du dessin.

Dans les deux conducteurs de courant *c d* (fig. 3) sont insérés, de façon à entrer en contact intime avec ces conducteurs, des organes en forme de fourche *e f*, dont chacun est muni d'une électrode à galet *g* ou *h*, facile à changer: on peut, d'ailleurs, disposer seulement l'électrode inférieure par exemple de façon amovible. De même on peut aussi donner à l'électrode inférieure ou supérieure seule la forme de galet mobile, tandis que l'autre électrode constitue le conducteur de courant établi d'une manière fixe.

Le galet *g* du conducteur supérieur *c* est claveté sur un axe *i* qui est muni d'une roue dentée droite *k*, sur laquelle le mouvement d'un volant à main *l* dissimulé convenablement peut encore être monté directement, c'est-à-dire sans transmission sur l'arbre *g*. En outre l'arbre *i* peut être muni de l'autre côté d'une roue dentée droite, d'une roue conique, d'une poulie de commande, etc., qui sert à actionner mécaniquement l'électrode à galet *g*, dans le cas où on désire un amenage automatique des objets qu'il s'agit de souder par une force motrice. Le volant à main est destiné à accélérer ou à retarder le mouvement de rotation du galet *g* suivant les besoins, ou bien à actionner en général le galet à la main. Le retard ou l'accélération du mouvement de l'axe *i*, lorsque le mouvement est produit d'une manière mécanique, peuvent naturellement être produits par d'autres dispositions mécaniques. La partie supérieure de la fourche qui porte l'électrode *g* est formée dans ce cas en crémaillère *n*, dans laquelle engrène un pignon *p*, monté au moyen d'un collier *o* sur le conducteur *c* et qui est claveté sur un arbre *q* dont l'extrémité extérieure est munie d'un levier *r* à poignée *f*. En élevant ou en abaissant le levier *r* on peut donc écarter ou rapprocher l'électrode à galet supérieure *g* de l'électrode à galet inférieure *h*. En outre on peut, en élevant ou en abaissant la fourche *f* dans le conducteur *d*, élever ou abaisser le galet inférieur amovible *h*.

Si alors on amene entre les deux électrodes à galet *g* les bords de la matière qu'il s'agit de souder et qu'on ferme le circuit, on peut obtenir de cette façon un soudage continu, c'est-à-dire une jonction non interrompue, tandis que l'électrode à galet supérieure *g* peut s'appliquer à volonté sur l'électrode à galet inférieure *h* qui est fixe, ou bien également mobile, de sorte que les deux bords de matière qu'il s'agit de souder se trouvent réunis d'une manière solide.

Au lieu d'amener successivement les objets qu'il s'agit de souder entre les électrodes on peut aussi disposer de façon à pouvoir se déplacer l'appareil électrique à souder en regard des objets fixes.

Lorsqu'il s'agit, par exemple, de souder des fers blancs seulement sur certains points on peut employer avantageusement l'appareil représenté à la fig. 5, dans lequel les électrodes *a* et *b* ont la forme de tenons. Les

teur *d*, tandis que l'électrode supérieure *b* est montée sur une chape *c*, qu'on peut faire tourner au moyen du levier à poignée *f* qui y est relié, autour de l'axe *g*, de telle façon que les pointes des électrodes *a b* se rapprochent ou s'écartent l'une de l'autre. Si alors on amène, par exemple, deux extrémités de fer-blanc qu'il s'agit de souder et qui se recouvrent réciproquement entre les électrodes et qu'on applique énergiquement celles-ci tout en produisant le courant, il se forme un petit point rond de soudure très net qui remplace parfaitement un rivet. Dans ce cas également on peut régler d'une façon exacte, c'est-à-dire maintenir dans les limites voulues, surtout pour des récipients minces qui n'ont pas à subir une pression très forte, la pression exercée sur le point de soudure au moment voulu.

RÉSUMÉ.

1° Un procédé pour la fabrication d'objets métalliques, surtout d'objets faits de feuilles métalliques extrêmement minces, par soudage électrique direct, caractérisé en ce qu'une électrode, ou les deux sont utilisées pour exercer avant ou pendant l'amenage du courant électrique, ou seulement pendant l'émission du courant, une pression de préférence exactement réglable sur le point où le soudage doit avoir lieu.

2° Deux électrodes en forme de galet, l'une ou autres, entre lesquels on introduit les objets à souder (fers-blancs ou autres), dont l'une peut être rapprochée ou écartée de l'autre au moyen d'un levier, excentrique ou autre dispositif, actionné par une crémaillère ou autre dispositif.

3° Pour permettre un soudage continu de joints longitudinaux, transversaux et circulaires, deux électrodes en forme de galet dont l'une ou les deux, maintenues sous une pression convenable, sont actionnées à la main ou au moyen de dispositifs mécaniques pour produire l'amenage de la pièce qu'il s'agit de souder, tandis que celle-ci peut aussi être tirée à travers les électrodes à galet, maintenues sous une pression convenable, une commande spéciale des électrodes à galet étant alors inutile.

FRENCH PATENT NO. 336,187—WILHELM EGEL—
October 13, 1903

Process and Apparatus for the Manufacture of Metallic Objects of All Kinds, Principally Objects of Extremely Thin Sheets, by Direct Electric Welding.

(DELIVERED JANUARY 7, 1904; PUBLISHED MARCH 1, 1904.)

The present invention consists in a process for the manufacture of metallic objects of all kinds, principally objects of extreme thin sheets, by direct electric welding. The new process consists in that one of the electrodes, or else both, do not serve only for conducting the electric current, but are also uesd to exert, before and during the turning on of the electric current, or else only at the moment of such admission, a greater or less pressure at the point at which the welding is to take place. In consequence, the member which conducts the electricity, constitutes, at the same time, the mechanical element, in such a way that much more favorable working conditions are obtained, because in all ordinary processes of electric welding, it is necessary, as is well known, to immediately energetically hammer or compress the point of welding, brought to the desired temperature, in order to obtain a satisfactory weld.

However, in none of the processes of electric welding now known are the bodies to be welded pressed during the operation solidly together by one of the electrodes or by both, to assist in the welding. Heretofore, no compressing action was exerted, or else it took place at a certain distance from the point where the welding was being done, but not by means of the electrodes themselves compressing directly the point to be heated. In fact, up till now, there has never been exerted a pressure, at the time of electric welding, by means of electrodes arranged in the direct line of the current, immediately above or at the welding surface or welding point.

To execute this process, various means may be made use of, because the necessary pressure at the welding point may be effected by means of any auxiliary mechanical devices, capable of producing or of transmitting a pressure, for example, by means of a press, directly or through lever transmission. However, this work may be performed, also, simply by means of hand levers or by means of direct or indirect manual action.

In the drawing:

Fig. 1 represents the welding, performed according to the present process, of two sheets of equal thickness, in an intermittent manner or in spots.

Fig. 2 is a front elevation.

Fig. 3 is a side elevation of a continuous electric welding device

in which the pressure action is exerted by roller electrodes, in such a way that the different points of the joints, which are to be welded, are successively united with a minimum consumption of current.

Fig. 4 represents the welding of the longitudinal joint of a hollow cylindrical or conical object according to the new process.

Fig. 5 is a side elevation of a welding device, already indicated in Fig. 1, and in which there are used, to exert the pressure, electrodes of forms shaped to suit the particular requirements, and which may be adapted for as small contact surfaces as required.

Fig. 6 represents two practical forms of electrodes which touch at their ends.

As shown in Fig. 1, the two metallic objects (tin or the like) are introduced with their ends overlapping between the two electrodes *a b*. One of these electrodes is applied lightly before the welding, or else only during the welding, as is indicated by an arrow, on the other electrode, or else the two electrodes may exert together a pressure on the objects to be welded.

To execute the process, when it relates to a continuous welding action for longitudinal joints, cross joints or circular seams, there may be advantageously employed the means shown in Figs. 2 and 3 of the drawing.

In the two current conductors *c d* (Fig. 3) are inserted, in such a way as to make contact with said conductors, members in the form of forks *e f*, each of which is provided with a roller electrode *g* or *h*, readily interchangeable; however, only the lower electrode, for example, may be made removable. Likewise, the lower or upper electrode only may be in the form of a movable roller, while the other electrode constitutes the current conductor formed of a stationary element.

The roller *g* of the upper conductor *c* is keyed upon a shaft *i*, which is provided with a spur gear *k*, to which the movement of a hand-wheel *l* is transmitted by means of a pinion *m;* the hand-wheel may also be mounted directly, that is to say, without transmission, on the shaft *g*. Furthermore the shaft *i* may be provided on the other side with a spur gear, a bevel gear, a driving pulley, etc., which serves to mechanically actuate the roller electrode *g*, when an automatic feed of the objects to be welded by power is desired. The hand-wheel *l* is designed to accelerate or retard the rotary movement of the roller *g* as needed, or else, generally, to actuate the roller by hand. The retardation or the acceleration of the movement of the shaft *i* when the movement is produced mechanically, can naturally be produced by other mechanical means. The upper part of the fork which carries the electrode *g* is formed in this case as a rack *n*, in which meshes a pinion *p*, mounted by means of a collar *o* on the conductor *c*, and which is keyed on a shaft *q*, the outer end of which is provided with a hand-lever *f*. By raising or lowering the lever *r*, the upper roller electrode *g* may be brought nearer to or further away frow the lower roller *h*. Fur-

thermore, by raising or lowering the fork *f* in the conductor *d*, the lower removable roller *h* can be raised or lowered.

Thus, if the edges of the material to be welded are brought between the two roller electrodes *g* and the circuit is closed, a continuous welding may be obtained in this manner, that is to say, an uninterrupted joint, while the upper roller electrode *g* may be applied as desired on the lower roller erectrode *h* which is fixed, or else also movable, so that the two material edges to be welded are united in a solid manner.

Instead of bringing the objects to be welded successively between the electrodes, the apparatus may be arranged so that it can be moved relatively to the stationary objects to be welded.

When it is required, for example, to weld sheets at certain points only, the apparatus represented in Fig. 4 (?5) may be advantageously employed, in which the electrodes *a* and *b* have the form of pins. The lower electrode *b* is inserted in the conductor *d*, while the upper electrode *b* is carried by an arm *s*, which can be turned by means of a hand-lever *t*, to which it is connected, around the shaft *u*, in such a way that the points of the electrodes *a b* are approached towards or separated from each other. If then, for example, two ends of sheet tin, which are to be welded and which overlap each other, are placed between the electrodes and the latter are firmly pressed together, while the circuit is closed, there is formed a small round point of weld, clearly defined, which takes the place of a rivet perfectly. In this case also, the pressure exerted on the point of weld at the desired moment can be controlled very exactly, that is to say, be maintained within the desired limits, especially for thin vessels which are not to be subjected to a very high pressure.

CLAIMS.

1. A process for the manufacture of metallic objects especially objects made of extremely thin metal sheets, by direct electric welding, characterized by the fact that one of the electrodes, or both of them, are utilized to exert, before or during the passage of the electric current, or else only during the admission of said current, a pressure preferably accurately controllable, at the point where the welding is to take place.

2. Two electrodes in the form of rollers, pins or the like, between which are introduced the objects (sheet tin or the like) to be welded, one of which electrodes may be approached towards or separated from the other by means of a lever, eccentric or other device, actuated by a rack or other means.

3. To permit a continuous welding of longitudnial, transverse and circular joints, two electrodes in the form of rollers, of which one or both, maintained under a suitable pressure, are actuated by hand or by means of mechanical means to produce the feed of the pieces to be welded, while the latter can also be drawn through the roller electrodes, maintained under suitable pressure, in which case a special control of the roller electrodes is unnecessary.

PATENTSCHRIFT

— № 50909 —

KLASSE 49: Mechanische Metallbearbeitung.

NIKOLAS von BENARDOS in ST. PETERSBURG.

Verfahren zur Bearbeitung von Metallen durch örtliche Erhitzung derselben mittelst Elektricität.

Patentirt im Deutschen Reiche vom 8. Mai 1889 ab.

Die Erfindung betrifft eine neue Anwendung des bekannten Joule'schen Gesetzes der Elektricitätslehre. Die zu bearbeitenden Metalle, vorzugsweise Stücke von geringeren Abmessungen, werden mit einem feuerbeständigen, verhältnifsmäfsig schlechten Leiter der Elektricität (Graphit, präparirte Kohle, Gemenge von Thonerde mit Kohle, Magnesium, Iridium, Kohle mit dünnen Metallüberzügen) in Berührung gebracht, während dieser Leiter von einem so starken elektrischen Strom durchflossen wird, dafs dieser Leiter diejenige Temperatur annimmt, welche für die beabsichtigte Bearbeitung der Metalle gerade erforderlich ist.

Es kann dieses Verfahren dazu dienen, verhältnifsmäfsig dünne Bleche und Stäbe gleichartiger oder verschiedenartiger Metalle unmittelbar mit einander zu verschweifsen, Metallverbindungen unter Anwendung eines Lothes auszuführen, metallene Gegenstände oder Theile derselben für den Zweck der Härtung auf eine bestimmte Temperatur zu bringen und gehärtete Gegenstände durch Erwärmung auf einen bestimmten Hitzegrad anzulassen.

Sowohl hinsichtlich des der Erfindung zu Grunde liegenden Gedankens, als hinsichtlich der Art der Anwendung unterscheidet sich dieses Verfahren wesentlich von dem von Benardos'schen Verfahren, die Metalle unter unmittelbarer Anwendung des elektrischen Lichtbogens zu bearbeiten, sowie von dem elektrischen Schweifsverfahren von Elihu Thomson.

Zur Anwendung des im Vorstehenden charakterisirten Erfindungsgedankens dienen eine Anzahl einfacher Vorrichtungen, aus deren Beschreibung die Eigenthümlichkeiten der Erfindung noch besonders ersehen werden können.

Um zwei dünne Bleche mit einander zu verschweifsen, werden dieselben durch ein biegsames Kabel mit dem einen Pol einer kräftigen Elektricitätsquelle von geringem inneren Widerstand in leitende Verbindung gesetzt. Mit dem anderen Pol dieser Elektricitätsquelle steht ein Löthkolben *K* (s. Fig. 1) in leitender Verbindung; dieser Löthkolben ist in der Hauptsache aus einem die Elektricität sehr gut leitenden Metalle (Kupfer) hergestellt und trägt an seinem unteren Ende in einer passenden Fassung ein kleines Stück *w* des die Elektricität schlecht leitenden, feuerbeständigen Materials; mit letzterem geschieht die Bearbeitung des Werkstückes.

Am anderen Ende ist der Körper des Löthkolbens mit einem Heft versehen, welches die Hand des Arbeiters gegen die Wirkungen der Wärme und der Elektricität schützt.

Sowie der schlechte Leiter *w* die zu bearbeitenden Metallstücke *A' A''* berührt, wird der Stromkreis geschlossen und ein beträchtlicher Theil der elektrischen Energie der Stromquelle wird im schlechten Leiter *w* in Wärme umgesetzt; *w* beginnt alsbald zu glühen. Durch Ausschalten von Widerstand aus dem Stromkreise mit Hülfe eines Rheostaten *C*, Fig. 1, wird die Temperatur des Stückes *w* so lange gesteigert, bis das zu bearbeitende Metall zu schmelzen beginnt. Alsdann wird unter mäfsigem Druck entweder der elektrische Löthkolben längs der herzustellenden Naht oder das zu bearbeitende Metallstück unter dem feststehenden Löthkolben fortbewegt.

die Arbeit beendet, so wird durch einen Ausschalter der Strom unterbrochen und hierauf der Löthkolben vom Metall entfernt.

Um den zu bearbeitenden Metallstücken eine sichere Unterlage zu gewähren, werden dieselben entweder auf eine feuerbeständige, die Wärme schlecht leitende Unterlage Asbest gelegt, oder ein derartiger schlechter Wärmeleiter wird durch eine geeignete Vorrichtung auf der anderen Seite gegen das Werkstück gepreßt. In gewissen Fällen kann es jedoch auch zweckmäßig erscheinen, durch Auflagerung der zu bearbeitenden Stücke auf eine die Wärme rasch abführende Unterlage, Metall, den Widerstand gegen den Druck des Löthkolbens herzustellen.

Bei manchen Arbeiten, für welche die vorliegende Erfindung zweckmäßig erscheint, wird es vorzuziehen sein, zwei sich gegenüberstehende Löthkolben zu verwenden, von welchen der eine mit dem positiven, der andere mit dem negativen Pol einer Elektricitätsquelle verbunden ist, während die beiden Löthkolben von einander isolirt sind.

Fig. 2 zeigt im Grundriß, Aufriß und Seitenansicht eine Vorrichtung, welche zur Ausübung des Verfahrens in dieser eben angedeuteten Weise geeignet erscheint. Zwei Löthkolben *K' K''* sind zu einer Art Scheere oder Zange vereinigt, und sind beide um eine Achse *C* drehbar. Durch isolirende Zwischenschichten wird der Uebergang des Stromes von einem Löthkolben zum anderen durch die Achse *C* unmöglich gemacht. Die Klemmen *D'* bezw. *D''* nehmen die Enden der mit den Polen der Elektricitätsquelle verbundenen biegsamen Kabel auf. Der Strom geht alsdann von *D'* über *K'* nach *w'*, von dem aus schlecht leitendem, feuerbeständigem Material hergestellten Stücke *w'* durch das zu bearbeitende Metall nach *w''* über und kehrt über *K''* und *D''*, durch einen Rheostaten hindurchgehend, zur Elektricitätsquelle zurück. Die Holzhefte der beiden Löthkolben sind wiederum *H' H''*. *F* eine Feder, durch welche die beiden Stücke *w' w''* zusammengepreßt werden.

In Fig. 3 ist eine der in Fig. 2 dargestellten sehr ähnliche Vorrichtung abgebildet. Die beiden Löthkolben werden hier von einem Ständer getragen, von dem sie jedoch durch nicht leitende Zwischenschichten isolirt sind. *D'* und *D''* sind wiederum die beiden Klemmen, welche die den Strom zu- und abführenden Kabel aufnehmen. Der obere Löthkolben besitzt bei *I* ein Scharnier, und *G* ist ein verschiebbares Laufgewicht, durch welches der obere Löthkolben gegen den unteren angedrückt wird. *F'* und *F''* sind zwei Führungsrollen oder auch zwei Walzen, welche außer zur Führung zur Glättung der Löthnaht dienen.

In Fig. 4 ist eine einfache Vorrichtung abgebildet, welche dazu bestimmt ist, stabförmige Gegenstände Ende an Ende zu verschweißen. Zwei Ständer *A' A''*, welche durch die Klemmen *D' D''* mit den Polen der Elektricitätsquelle verbunden sind, tragen oben zwei durch Scharniere befestigte Deckel *B' B''*. In diesen befinden sich Stücke schlecht leitenden, feuerbeständigen Materials *w' w''*, zwischen welchen der Strom von dem einen zum anderen Ständer übergeht. Diese Stücke schlecht leitenden Materials stehen zwar das eine mit dem Metall des einen Ständers, das andere mit dem Metall des anderen Ständers in leitender Verbindung; um denselben aber bei geringem Querschnitt eine angemessene Widerstandsfähigkeit zu geben, sind dieselben durch eine Schicht feuerbeständiger Chamotte- oder Speckssteine in die Deckel *B' B''* eingepaßt. Die Stücke schlecht leitenden Materials besitzen eine dem Querschnitt des zu bearbeitenden Stückes angemessene Nuth.

Läßt man einen elektrischen Strom in *D'* eintreten, so geht derselbe über *A'*, durch das schlecht leitende Stück *w'*, durch das Werkstück *E* nach *w''* und von da nach *A''* über und tritt durch *D''* wieder aus. Die Stücke *w' w''* werden hierbei glühend und bewirken das Erhitzen des zu bearbeitenden Metallstückes *E*.

Fig. 5 stellt eine ähnliche Vorrichtung dar, dazu bestimmt, Drähte Ende an Ende zu verschweißen. Die zu verbindenden Drahtstücke werden zwischen die aus schlecht leitendem, feuerbeständigem Material hergestellten Backen von passender Form *w' w''* gebracht, durch welche, wie bei den vorher beschriebenen Einrichtungen, der Strom hindurchgeht. Bei *E* trägt dieser Apparat eine Feder, durch welche der obere Backen gegen den unteren gepreßt wird. Um den Verlust an Stromwärme durch Strahlung zu vermindern, ist der Haupttheil des Apparates von einem feuerbeständigen, isolirenden und schlecht Wärme leitenden Mantel *M* umgeben, der mit zwei Oeffnungen versehen ist, um dem Werkstück den Durchgang zu gestatten.

In Fig. 6 ist eine Einrichtung abgebildet, welche sich dadurch von den vorhergehenden unterscheidet, daß der Strom nicht durch das zu bearbeitende Metall selbst hindurchgeht. Der elektrische Löthkolben wird vielmehr dadurch hergestellt, daß der elektrische Strom in ähnlicher Weise ein Stück schlecht leitenden Materials durchfließt, wie den Faden einer Glühlampe, und dadurch das schlecht leitende Material zum Glühen bringt. In Fig. 6 sind zwei solche parallel geschaltete Löthkolben *K'* und *K''* zu einer Löthzange vereinigt. Zwischen den beiden durch den Strom zum Glühen gebrachten Stücken schlecht leitenden Materials *w'* und *w''* werden die zu bearbei-

1150

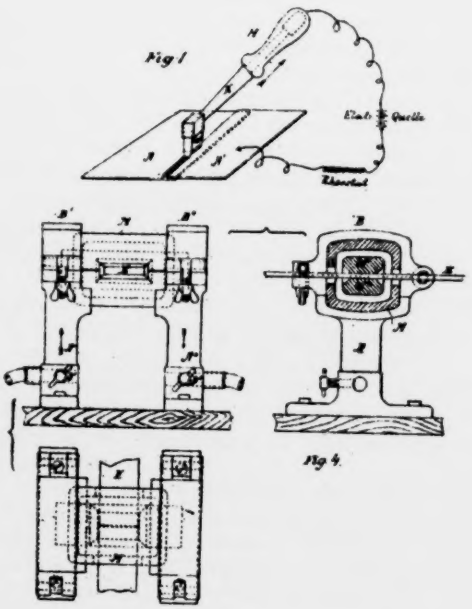
50909

enden Metallstücke von Hand oder durch zur Leitrollen *F* und *F*¹ hindurchgeführt. Diese Anordnung hat den Vorteil, dafs man die Zange öffnen bezw. das zu bearbeitende Metall von der Lötvorrichtung entfernen kann, auch wenn der Strom nicht vorher unterbrochen wird, ohne dafs ein elektrischer Lichtbogen oder elektrischer Funke zwischen Metall und Lötvorrichtung gebildet wird.

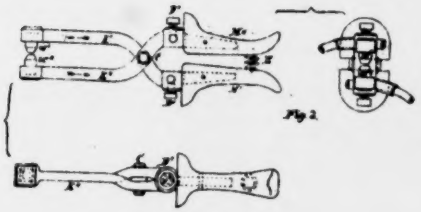
PATENT-ANSPRÜCHE:

1 Verfahren zur Bearbeitung von Metallen durch örtliche Erhitzung, welche man dadurch hervorruft, dafs durch elektrische Stromwärme Körper, die aus schlecht leitendem Stoff Graphit, Kohle, Gemenge von feuerbeständigen, nicht leitenden und leitenden Massen hergestellt sind, glühend gemacht und mit diesen das zu bearbeitende Werkstück in Berührung gebracht wird.

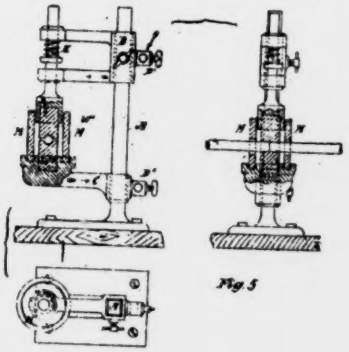
2 Zur Ausführung des durch Anspruch 1. gekennzeichneten Verfahrens:



a die in Fig. 1, 2, 3, 4 und 5 dargestellten Vorrichtungen, welche zur Verschweifsung und Verlötung gleichartiger oder verschiedenartiger Metalle oder zum Härten bezw. zum Anlassen von Körpern dienen können und dadurch gekennzeichnet sind, dafs ein elektrischer Strom feuerbeständige, schlecht leitende Körper zum Glühen bringt, indem er durch diese und durch das zu bearbeitende Werkstück selbst hindurchgeht;



b die in Fig. 6 abgebildete Erfindungsvorrichtung, welche darauf beruht, dafs das zu bearbeitende Werkstück mit einem oder mehreren durch elektrischen Strom glühend gemachten, feuerbeständigen, schlecht leitenden Körpern in Berührung gebracht wird, ohne dafs dabei dieser elektrische Strom durch das Werkstück selbst hindurchgeht.



Hierzu 1 Blatt Zeichnungen.

TRANSLATION OF GERMAN PATENT No. 50,909, NIKOLAS VON BENARDOS.

Patented from May 8, 1889; Issued February 19, 1890.

Process of Working Metals by Heating Them Locally by Electricity.

This invention relates to a novel application of the well known JOULE'S law of electrotechnics. The metals to be worked, preferably pieces of small dimensions, are brought into contact with refractory material which is also a relatively bad conductor of electricity, (for example, graphite, prepared carbon, mixture of clay with carbon, magnesium, iridium, carbon with thin metal coatings,) while said conductor is traversed by an electric current of such strength that it will heat said conductor to that temperature which is exactly required for the desired working of the metals.

This process may serve to directly weld together relatively thin metal sheets and rods, of one and the same or of different metals; to the joining of metals with the use of a solder; to heating metal objects or parts to a definite temperature for the purpose of hardening them, and to annealing hardened objects by heating them to a certain temperature.

This process is clearly distinguished, both from the point of view of the inventive idea on which it is based and from that of its mode of operation, from the prior Benardos process working metals by the direct employment of the electric arc, as well as from the electric welding process of Elihu Thomson.

In putting into practice the inventive idea stated above a variety of simple apparatus may be used, from the description of which the distinguishing characteristics of the invention will be more particularly understood.

To weld together two thin sheets, they are conductively connected by a flexible cable with one pole of a powerful source of electricity of low internal resistance. With the other pole of said source of electricity is conductively connected a welding tool (soldering iron) K, (see Fig. 1,) which is made principally of a metal (copper) which is a very good conductor of electricity, said tool carrying in a suitable holder at its lower end, a small block w of heat refractory material which is also a bad conductor of electricity; it is this block which performs the operations on the metal.

At its other end the body of the tool is provided with a handle of insulating material (wood) to protect the hand of the workman from the effects of the heat and electricity.

The bad conductor w being brought into contact with the pieces of work A', A'', the circuit is closed and a considerable portion of the electrical energy is converted into heat in the bad conductor w, which immediately begins to glow. By cutting resistance out of the circuit with the aid of a rheostat C, Fig. 1 the temperature of the block w is raised until the metal of the work-pieces begins to

melt. Then, while heavy pressure is applied, either the tool is moved along the joint or else the work is moved under the stationary tool. When the joint is welded, the circuit is interrupted by a circuit breaker and the tool is removed from the work.

To provide a safe backing for the work pieces, they are either laid upon a fireproof support which is a poor conductor of heat (asbestos), or else such a bad heat conductor is pressed against the work on the other side from the tool by any suitable mechanism. In certain cases, however, it may be of advantage to make the backing support of the work which resists the pressure of the tool, of material (metal) which conveys heat away rapidly.

For some kinds of work to which the present invention is applicable, it may be advantageous to employ two opposed welding tools, one of which is connected to the positive pole, and the other to the negative pole of a source of electricity, the two tools being insulated from each other.

Fig. 2 shows, in plan, elevation and end view, an apparatus designed to carry out the process in the manner just described. Two welding tools K', K", are united in the manner of a pair of shears or tongs, both being oscillatably mounted on the pivot C. The current is prevented from passing from one tool to the other through the said pivot by the interruption of insulating material. Binding screws D', D", receive the ends of the flexible cables connected to the poles of the source of electricity. The current thus flows from D' through K' to w', from this block of refractory and poorly conducting material through the metal of the work to block w'', and returns through K" and D" and through a rheostat to the source of electricity. H' and H" are the wooden handles, and E is a spring by which the two blocks w' and w'' are pressed together.

Fig. 3 represents an apparatus which is very similar to that shown in Fig. 2. The two tools are here mounted on a standard from which they are insulated by suitable material. D' and D" are here again the binding screws to which the current conductors are connected. The upper tool is hinged at I and G is a sliding weight by which the upper tool is pressed against the lower one. F', F" are two feed rollers, or else rolls which serve to smooth the joint as well as to feed and guide the work.

Fig. 4 illustrates a simple apparatus designed for welding rod-shaped objects end to end. Two standards A', A", which are connected by binding screws D', D", with the poles of the source of electricity, carry at their top two hinged covers B', B", containing blocks w', w'' of heat refractory material which is a poor conductor of electricity, between which the current flows from one standard to the other. These blocks of poorly conductive material are in connection, one with the metal of the one standard and the other with the metal of the other standard; in order to give them sufficient resistance when of small section, they are enclosed in jackets of refactory firebrick or soapstone in the covers B', B". The blocks of poorly conductive material are grooved to fit the work.

When an electric current enters at D', it flows through A', poorly conductive block w' and the work E' to block w'', thence through A'' and out at D''; the blocks w', w'' are thereby caused to glow and cause the heating of the metal piece E to be treated.

Fig. 5 shows a similar apparatus designed for butt welding wires; The wires to be joined are placed between the jaws w', w'' of heat-refractory and poorly conductive material and of suitable shape; the current flows through them as before. This apparatus comprises a spring E by which the upper jaw is pressed against the lower. To reduce the loss of heat by radiation, the main part of the apparatus is enclosed by a jacket M, of refractory, insulating and non-conducting material, the jacket having suitable openings for the work to pass through.

Fig. 6 illustrates an apparatus which is distinguished from those hereinbefore described in that the current does not pass through the work itself. The electric tools are so constructed that the current flows through and heats up a block of poorly conductive material, as it does in the case of electric lamp filaments, and thus raises the poorly conductive waterial to a glowing heat. In Fig. 6, two pairs of such tools K' and K'' are parallelly mounted and combined in a welding tongs. Between the two poorly conductive blocks w', w'', heated by the current to incandescence, the work is fed by hand or by rollers F', F''. This form of apparatus has the advantage that the tongs can be opened and the work removed without the circuit having been opened, for no electric arc or spark will be formed between the work and the tools.

CLAIMS.

1. Process of working metals by local heating, the heat being generated by raising to incandescence, by the passage of an electric current, blocks of poorly conductive material (graphite, carbon, mixtures of fireproof, non-conducting and conducting substances), and bringing the piece to be worked into contact with said blocks.

2. To carry out the process defined in claim 1: (a) The apparatus represented in Figs. 1, 2, 3, 4 and 5, which can serve for welding and soldering the same or different kinds of metal, or for hardening or annealing objects, and which are characterized by the fact that an electric current raises to incandescence fireproof, poorly conductive bodies, by flowing through the same and through the work-piece to be treated itself.

(b) The inventive apparatus represented in Fig. 6, which is based on the arrangement whereby the work-piece to be treated is brought into contact with one or more fireproof, poorly conductive bodies, raised to incandesence by an electric current, without that said electric current flows through the work-piece itself.

PETITION and POWER

To the Commissioner of Patents,

UNITED STATES of AMERICA.

Your Petitioner Johann Harmatta Engineer, a subject of the King of Hungary residing at Szepesvaralja, in the Kingdom of Hungary prays that Letters Patent of the United States be granted to him for the Improvements in Electric Welding set forth in the annexed specification:

And he hereby appoints Messrs Marion and Marion (J. A. Marion & J. Wilfrid Marion) of Montreal, Province of Quebec, Canada, and Washington, D.C., U.S.A., his Attorney with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign his name to the drawings, to receive the Letters Patent when issued, and to transact all business in the Patent Office connected therewith.

Signed at Budapest, Hungary this 5th day of November, 1903

Johann Harmatta

Address communications to MONTREAL OFFICE

Specification.

To all whom it may concern:

Be it known that I, Johann Harmatta, Engineer, a subject of the King of Hungary, residing at Szepesvaralja, in the Kindom of Hungary, have invented new and useful "Improvements in Electric Welding", of which the following is a specification.

My invention relates to a process of and apparatus for manufacturing metal articles of all kinds, in particular those of the thinnest sheet metal, by direct electric welding. The new process consists in one of the electrodes (or both of them) not only serving to feed the current, but also being employed for exercising a more or less strong pressure either before and during the period of supplying the electric current, or only at the moment of this supply, at the place at which the welding is to be done. The member which feeds the electricity is thus at the same time the tool, and in this manner the most favorable con-

ditions of working possible are secured, since, as is well known, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough.

According to none of the present known electric welding processes are the articles to be welded firmly pressed together during the welding operation by one or both electrodes, for the purpose of favoring welding. Hitherto either no pressure has been exerted at all, or it has been exercised at a certain distance from the place of welding, or at all events not centrally direct upon the electrodes pressing on the place to be heated. In short, hitherto direct electric welding pressure has never been exercised by means of the electrodes located in the direction of the current directly above the surface or point being welded.

For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place of welding by the aid of any of those technical means which are suitable for producing or transmitting pressure; e. g., with a press either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power.

In the accompanying drawing

Fig. 1 is a view illustrating the welding of

two metal sheets of equal thickness, intermittently or at certain spots only. 1159

Fig. 2 is a front elevation and

Fig. 3 a side elevation of a device which may be employed for continuous welding, the pressure being exerted by roller electrodes, whereby the advancing series of single points of the seam to be welded is united to a whole with a minimum consumption of current.

Fig. 4 illustrates the method of welding the longitudinal seam of a cylindrical or conical hollow article according to my new process.

Fig. 5 is a side elevation of a welding device (also illustrated in part in Fig. 1) according to which the pressure is exercised by pin shaped electrodes, the form of which may be suited to the particular purpose in view, and which may be adapted to work on the smallest possible surface of contact.

Fig. 6 shows two forms which may be adopted for the ends of the contacting electrodes.

As Fig. 1 shows, the two sheet metal or other bodies, the edges of which lie upon each other, are introduced between the two electrodes *a b*. Of the latter the one, somewhat prior to welding or only during the welding operation, is pressed upon the other, as the arrow shows; or both electrodes may be caused to exert pressure on the objects to be welded.

For continuous welding of longitudinal, cross and circular seams, the device shown in Figs. 2 and 3 of the drawing may be advantageously employed.

In the two conductors *c d* (Fig. 3), forked members *e f*, making intimate contact with the conductors, are introduced, each furnished with a removable roller electrode *g* and *h*; or, if desired, only the lower roller electrode, for instance, may be capable of being removed. Or the lower or upper electrode may be formed as movable roller and the other electrode forms a stationary conductor.

The roller *g* of the upper conductor *c* is keyed to an axis *i* carrying a spur wheel *k* to which the motion of a suitably mounted hand-wheel *l* can be transmitted by means of a spur wheel *m*. Or the hand-wheel may be mounted directly on the shaft *g*, without the use of any intermediate gear-wheels. Or the axis *i* may have on the other end also a spur or bevel wheel, or pulley or the like for driving the roller electrode *g*, should it be desired to automatically advance the object being welded by means of motor power. The purpose of the hand-wheel is to accelerate or decrease the speed of rotation of the roller *g*, as may be required, and in general to actuate the roller by hand for any purpose. The axis *i* may, of course, be caused to move slowly, as in the case of mechanical power, by any other suitable means. The

upper part of the fork carrying the electrode roller *g* is here shown as constituting a toothed rack *n*, in which engages a pinion *p* carried by the conductor *c* by means of a ring-holder *o*. The pinion *p* is keyed to the axis *g*, which carries a hand lever *r* at its outer end. By raising or depressing the lever *r*, the upper roller electrode *g* may be separated from or advanced towards the lower roller electrode *h*. Furthermore by raising or depressing the forked piece *f* in the conductor *d* the lower removable roller *h* may be adjusted higher or lower.

If now the ends of the objects to be welded are introduced between the two roller electrodes *g h* and the circuit closed, continuous welding may be undertaken, that is to say an uninterrupted welded seam made, whereby the upper rotary roller electrode *g* may be pressed with any required degree of pressure upon the lower stationary (or rotary) roller electrode *h*, so that the two ends of the material to be welded are firmly connected with each other.

Instead of the objects to be welded being introduced gradually between the electrodes. the electric welding apparatus may be arranged to slide relatively to the stationary objects.

Thus if it is required to weld, for instance, sheets of metal only at particular places, the apparatus shown in Fig. 5 may be advantageously employed,

1162

the electrodes *a b* having the form of pins. The lower electrode *b* is then inserted in the conductor *d*, whilst the upper electrode *a* is carried by an arm *s* by means of a hand-lever *t* carried by said arm *s* and can be turned on the shaft *u* in such manner that the points of the electrodes *a b* approach and recede from each other. If then two superposed sheet metal ends to be welded together are introduced between the electrodes, and the latter then firmly pressed together and the circuit closed, a small round, very sharply defined place of welding is caused which perfectly answers the purposes of a rivet. In this event, also, especially in the case of thin vessels which are not required to withstand great pressure, the pressure on the place of welding may act at the right moment be exactly regulated or kept within the proper limits.

2 words interlineated

Having thus described my invention, what I claim as new and desire to secure by letters patent is:—

1. The process of electric welding, consisting in employing the electrodes not only to conduct the current to the objects being welded, but also to exert a regulable pressure on the same, substantially as described.

2. An electrode apparatus for electric welding, comprising two electrodes between which the objects to be welded are introduced, and means whereby one of the

electrodes can be approached to and receded from the other, substantially as described.

3. An electrode apparatus for electric welding comprising two roller electrodes between which the objects to be welded are introduced, and means for pressing the electrodes to the work, substantially as described.

4. An electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, means for pressing the electrodes to the work, and means for rotating one or both of the rollers for the purpose of advancing the work in its path between the electrodes, substantially as described.

In Witness whereof I have hereunto signed my name this 5th day of November, 1903, in the presence of two subscribing witnesses.

APPLICATION FOR UNITED STATES PATENT.

PETITION WITH POWER OF ATTORNEY.

To the Commissioner of Patents:

Your petitioner Sebastian Ziani de Ferranti, a subject of the King of Great Britian and Ireland, residing at 31, Lyndhurst Road, Hampstead, London. N.W., England, whose Post Office address is 31, Lyndhurst Road, Hampstead, London, N.W. England, prays that Letters Patent may be granted to him for Process ~~and Apparatus~~ for Electrically Welding Turbine Blades to their Carrying Elements set forth in the annexed specification; and he hereby appoints Messrs. Spear, (Ellis Spear, Walter Donaldson, F.L.Middleton J.M.Spear) Middleton, Donaldson & Spear, of 1003, F,Street, N.W. Washington, D. C., United States of America, his attorneys with full power of substitution and revocation, to prosecute this application, make alterations and amendments therein, to receive the Patent, and to transact all business in the Patent Office connected therewith.

per G.

Sebastian Ziani de Ferranti

1170

TO ALL WHOM IT MAY CONCERN:

BE IT KNOWN THAT I, Sebastian Ziani de Ferranti, a subject of the King of Great Britian and Ireland, and residing at 31, Lyndhurst Road, Hampstead, London N.W., England, have invented a certain new and useful ~~Bladed turbine element and process for the manufacture thereof, Process and Apparatus for Electrically Welding Turbine blades to their carrying elements~~ Process for Electrically Welding Turbine Blades of which the following is a specification:

Apr. 30-09
Oct. 10, 1905
per P

The invention relates to the electrical welding of turbine blades on to the wheels, rings or drums carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an inexpensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine balde to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier, rapidly conducts heat away from the welding point thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

pt. 27, 1904 The ~~first part of the~~ invention, therefore, consists broadly in adjusting the volume of the blade carrying element in the neighbourhood of the welding point so that approximately equal heating occurs in both faces to be welded.

~~The second part of the invention consists in a machine whereby the methods forming the first part of the invention can be carried into effect with great rapidity and accuracy.~~

(It will be seen that all the edge views in the preceding figures are shown as developments for clearness of drawing and not as true projections.)

Figures 12 and 13 show a side elevation and plan respectively of the greater portion of the machine;

Canceled Sept. 27,1904. Figure 14 is an end view partly in section, as seen from the right in figure 12,

Figure 15 showing an end view of the welding head but as seen from the left in figure 12;

Figure 16 shows an elevation of the slotting attachment supposed removed in figure 12;

Figures 17 and 18 show sectional elevation and plan respectively of the automatic stopping gear;

Figures 19 and 20 show side and views respectively of a form of blade holder having a mechanical clamping device,.

Figures 21 and 22 being similar but with the clamping device operated electromagnetically.

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

Sept. 27, 1904. In carrying out the ~~first part of the~~ invention according to the form shown in figures 1 and 1a, the turbine wheel or disc is shown at a, cross grooves, b,

being cut in its circumferential edge so as to leave projecting portions of metal, e, to which the turbine blades, d, are welded.

The same object is attained by cutting two intersecting sets of grooves, g, in the edge of the disc, as shown in figure 2, or by cutting circumferential grooves, such as f, completely around the edge (see figures 3 and 3a.)

Figure 4 shows the invention according to one form applied to the case of a drum blade carrier, a'; the drum is grooved circumferentially with grooves, f', the intervening collars of metal being then cross-cut to form projecting teeth, e', on which the blades are welded.

According to a modified form, radial holes, h, may be bored a short distance into the edge of the disc, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in figure 5, or arranged without particular reference to the position of the blades, (see figure 6).

In figure 7, a method is shown of removing metal in the neighbourhood of the welding point by boring holes, i, through (or partly through) from face to face of the disc at a radius slightly less than that of its outside edge.

The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, whilst at the same time leaving sufficient areas untouched to ensure the mechanical strength in the welded joint.

Referring now to figures 8 and 8a, a form of wheel is shown somewhat diagrammatically which is built up of two dished discs, k, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as l, disposed at a radius somewhat less than the maximum radius of the discs, the blades, d, being welded in position on their outside edges.

Figures 9 and 9a show a type of wheel generally similar to that last described but having an intermediate plane disc, m, in addition to the two dished discs, k; a portion, n, of the hub, o, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, l, are indicated as before but any other convenient method of holding the discs in their correct relative position may be adopted.

Insert H 2

In figures 8 and 9, the dished discs, k, are indicated as secured to the hubs, o, by pressing the inner edges of these discs into grooves and subsequently burring over the hubs to hold the discs in place.

In the modification shown in figures 10 and 10a, two dished discs, k, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, b, being cut in their edges in accordance with the method described above with reference to figures 1 and 1a. Again, that portion of the disc carrying the blades may be built up of a set of thin laminae, r (see figure 11) the edges of which are notched as at s, the laminae being assembled in such a way that the notches, s, are "stepped" with regard to each other, so that the intervening projections of metal may follow the shape

of the turbine blades to be welded to them.

Instead of notching the laminae, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

pt. 27, 1904. In ~~the first part of the~~ an such as the present invention, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

wert F1
r. 19, 1904.
wert G1

In carrying the second part of the invention into effect according to one form as shown in the drawings applied to the welding of blades upon a turbine wheel, t, the blade to be welded is held between renewable copper jaws, u, between which it is inserted so as to abut against a suitable stop, Y, these jaws being of suitable shape fixed by screws to the copper jaw holder, w. Details of the jaw holder together with methods of clamping the blades are hereinafter described with reference to figures 8 to 11, 19 22. The shank or end of the jaw holder remote from the blade is made cylindrical and clamped in a cylindrical bearing having a copper cap, x, suitable connected to one pole of transformer, battery or the like. The jaw holder may be clamped in its cylindrical bearing in any position to suit the setting angle of the blades, a wedge such as z, of the necessary taper, being preferably inserted between the jaws holder, w, and a planed surface on the cross-head, 2, carrying the

nceled
pt. 27, 1904.

cylindrical bearing, thus ensuring the correct angle and safeguarding against its alteration.

The crosshead, 2, works in a slide, 3, and is held in position by slide bars, 4; the lower face of the slide is inclined and co-operates with a corresponding inclined face formed on the welding head casting, 5, thus providing means for giving a delicate vertical adjustment to the crosshead. Studs or the like passing through slots in the welding head and nuts, 6, are provided for clamping the slide in place.

The pressure at the weld is obtained by means of an adjustable spring, 7, acting through a toggle, formed by the double link, 8, on the crosshead 2, and one leg, 9, of a bell crank pivoted on the welding head, 5. A rod, 10, connected to the toggle centre serves to transmit the pressure of the spring, 7, an adjustable stop, 11, being provided to limit the downward movement of the toggle centre. The rod, 10, passes through the spring, 7, and is provided at its upper end with a slot through which passes the tail end of a catch lever, 12, pivoted on the welding head; the pressure of the spring is transmitted to the catch lever through an adjustable set-screw, 13, projecting into the slot. This method obviates any side pressure and consequently friction on the toggle-rod.

The automatic switch, which is of the oil break pattern, is operated from a pair of levers, 14, pivoted on the welding head, by means of the spindle, 15.

A downward pull on the outer end of this double lever, 14, forces the switch on to its contacts against the pressure of a strong spring, 16, and also straightens out the links, 17, above, so that a catch piece, 18, fastened to one of these links, moves under and is

caught by the end of the catch lever, 12, thus retaining the switch in the "on" position. The switch is pulled on automatically as the welding head (operated in a manner to be described) reaches the back end of its stroke, by a bell crank lever, 19, one leg of which comes in contact with a fixed adjustable stop, 20, while the other is linked to the outer end of the double lever, 14, by means of the rod, 21.

The switch (see also figure 14, in which the rod, 21, is removed and the oil well wall partly broken away) is insulated from the levers, 14, by means of the fibre block, 22, forming part of the switch spindle 15, which is carried down into the oil well, 23, conveniently cast in one with the welding head. Two sets of contacts are provided, the upper or primary, 24, being preferably formed of laminated strips of copper; the lower or secondary contacts, 25, are arranged to make contact first and break last, this action being ensured by means of the light spring, 26. The break of the secondary contacts takes place in oil, thus preventing any arcing at the primary contacts. The main contact blocks, 27, to which the leads are connected, and the secondary contacts, 28, are mounted on an insulating ebonite base, 29.

To free itself from a blade that has just been welded, so that the turbine wheel or ring may rotate into position for the next weld, the welding head, 5, travel back in a slide formed in the box casting, 30, which is insulated from the main frame, 31, of the machine, in relation to which it is adjustable by means of studs and slots, adjusting screws or the like means, so that it can be secured in any position to suit different sizes of turbine wheels and lengths

of blades. Slide bars, 32, (see figure 15) constrain the motion of the welding head. This motion of the welding head is taken from a worm, 33, and worm wheel, 34, a sprocket wheel, 35, mounted on the worm wheel shaft, and chain, 36, serving to transmit the motion to a second sprocket wheel, 37, which together with a crank, 38, is mounted on the spindle, 39, this crank being linked to the welding head by means of the connecting rod or pitman, 40. The position of the bracket, 41, carrying the worm wheel, 34, and sprocket wheel, 35, can be adjusted to correspond with that of the box casting, 30. The worm, 33, is driven through a feather by the shaft, 42, the motion of which is so controlled (in a manner to be hereinafter described) as to cause the crank, 38, to make half revolutions alternately backwards and forwards, at the end of each of which the shaft, 42, stops automatically. The sprocket wheel, 37, is insulated from the welding head by means of the fibre ring, 43, seen in figure 15.

Spring buffers, 44, are provided at the left hand end (as seen in figure 12) of the box casting, 30, to take up all back lash in the various joints and ensure a steady pressure at the welding point.

As the welding head approaches the back of its stroke, the switch is closed automatically as mentioned above and the rod, 45, pivoted to the end of the leg, 46, of the toggle bell crank, strikes against the fixed adjustable stop, 47, and causes the toggle centre to rise, thus drawing the blade holder backwards. The leg, 46, of the toggle bell crank is then caught and held by the trip lever, 48, pivoted on the welding head. This lever, 48, is tripped by the crank at both ends of the stroke but at the back end

it is arranged that the toggle bell crank shall be held by the rod, 45, and stop, 47, till after the crank is clear, so that the welding head moves forward with the trip lever, 48, in gear.

The full cycle of operations is thus as follows:- The blade to be welded, having been placed in the jaws, 4, with the welding head in its backward position, the shaft, 42, is started with the switch in the "on" position and both the trip or catch levers, 48 and 12, in gear. The shaft, 42, is stopped automatically (in a manner to be explained) as the blade reaches the turbine wheel and at the same time, the crank, 38, trips the lever, 48, thus freeing the toggle bell crank and allowing the spring, 7, to produce pressure on the weld. The electric current may be controlled by an independent switch under the control of the attendant or this switch may be kept closed during the whole operation, in which latter case the welding starts simultaneously with the tripping of the trip lever, 48. As the blade softens under the heat, the pressure of the spring, 7, causes a slight shortening of the blade, this shortening being greatly magnified by the toggle and causing a comparatively large movement of the rod, 10, which descends and trips the catch lever, 12, thereby leaving the spring, 16, free to act to open the switch. The shaft, 42, is then reversed and the welding head returned to the back end of its stroke, where it is again stopped automatically after switching on the current and setting the trip lever, 48. The adjustable stops, 11 and 13, enable the machine to be set to break contact at the exact time when the shortening of the blade corresponds to a satisfactory weld.

In addition to carrying out the operations described above, an automatically operated attachment is preferably provided whereby the wheel or disc is prepared by slotting, drilling and the like in advance of the weld as regards position on the wheel and without slackening the progress of the welding operation, the machine thus taking a plain wheel or disc and doing all that is necessary to it until it appears as a finished article with all the blades welded on.

If the turbine wheel, 1, is to be prepared by slotting, for example, the slotting head, 49, (see figure 16 where the slotting attachment is shown removed from the machine) is constrained to move in a casing or frame, 50, forming a vertical slide and having a slotted flange, 51, at the base, by means of which it can be adjusted tangentially and bolted to the bed or frame, 31, of the machine; a slot in this frame also enables it to be adjusted longitudinally within the limits of the machine, so as to suit different sizes of turbine wheels. The cutting is done by one or more serrated cutters, 52, carried by the slotting head, the serrations being arranged in steps so that each tooth cuts deeper than the preceding one. In figure 13, two such cutters are indicated, the one being arranged in advance of the other as regards depth of cut. The slotting head is reciprocated by means of an internal screw, 53, engaging with a square nut, 54, fitting in a corresponding recess in the slotting head, 49, the screw, 53, being driven off the main motion shaft, 42, through bevel wheels, 55, one of which is slidably mounted on the shaft, 42, and is driven by a feather, the bracket, 56, which holds this wheel in position being adjustable long-

itudinally to correspond with different positions of the gearing. A clamp, 57, is provided to prevent the wheel vibrating as the cut is taken, this latter operation taking place as the welding head moves forward. After a new blade is welded in place, the motion of the shaft, 42, is reversed, thus causing the welding head to return and withdrawing the serrated cutters through the slots they have just formed. It is not until the cutters are well clear of the turbine wheel, that is to say, not until the welding head is toward the back end of its stroke that the automatic gear is operated to turn the wheel into position for the next weld.

This operation is effected by a rod, 58, passing through a hole in the welding head casting and having adjustable stops, 59, fixed to it. The rod actuates a crank, 60 fixed to it carrying a spring pressed pawl, 61, which co-operates in the usual manner with a ratchet wheel, 62, the motion of this wheel being transmitted by suitably proportioned gear wheels, 63, to the last wheel, 64, of the train, to which the turbine wheel is secured by means of the clamping plate, 65.

The dividing motion mechaniam just described is supported on a suitable stool, 66, which may itself be adjustable with regard to the bed plate, if desired.

The necessary adjustments to allow for different blade spacings are preferably made by altering the ratchet wheel, 62, or by setting the movable stops, 59, so as to cause the pawl, 61, to take the required number of teeth, and leaving the gear wheels, 63, 64, unchanged.

Referring to figures 17 and 18, the method of controlling the motion of the shaft, 42, will now be

described.

To the end of the main shaft, 42, a hollow prolongation of sleeve, 67, is rigidly secured, this sleeve being supported in suitable bearings, 68, and containing in its centre an easily fitting steel rod, 69. On the sleeve, 67, two loose pulleys, 70, 71, are mounted, adapted to run in opposite directions, the bosses of these pulleys being coned to form the male elements of friction clutches. The corresponding female clutches, 72, 73, slidably mounted on the sleeve, 67, are secured to the central rod by cotters, 74, which pass loosely through slots, 75, in the sleeve, 67. Thus a pull on the central rod in either direction will engage one or other of the clutches and the corresponding pulley will then drive the shaft.

As the gear is arranged in the machine described above, it is necessary for the shaft to make twenty revolutions only in the one direction, then to stop automatically and when started again by the attendant, to make exactly twenty more revolutions in the other direction and so on. This is provided for as follows:-

An extension, 76, of the central rod, 69, outside the sleeve, 67, is screwed and engages with a nut, 77, which is prevented from rotating by means of a suitable flat surface formed upon it. As the rod, 69, rotates, the nut, 77, travels along the rod until it comes in contact with one or other of the fixed adjustable stops, 78, through the centre of each of which the rod loosely passes. The nut, 77, being prevented from travelling further, any continuance of the sleeve's rotation, causes the central rod, 67, to be drawn through the nut, thus releasing the particular driving clutch engaged and stopping the shaft, 42.

It is impossible for the attendent to start the shaft again in the same direction, but by pulling the central rod a little further in the same direction as it was drawn by the nut, the other clutch will engage and the shaft run backwards until automatically stopped as before. For the purpose just mentioned, a forked starting handle, 79, pivoted on the bracket, 80, and engaging with collars, 81, in the central rod, is provided.

The two loose pulleys are preferably of different sizes, so that a slower speed is given to the main shaft when the slotting head is cutting than when it is returning.

It will be understood that the automatic stopping mechanism just described is shown detached from the rest of the machine in plan and elevation merely for convenience in drawing as it is preferably mounted on the same rigid frame work as the welding head and other parts above described as indicated in end view in figure 14.

Referring now to figures 19 and 20, details are given of the jaw holder already referred to in the general description of the machine, the stop, Y, alone being omitted.

According to the form illustrated, the jaw holder, W, is provided at the end remote from the blade with a circular shank, 62, which is clamped in its bearing at any suitable angle as already described. The blade end of the jaw holder is separated into two branches by means of the slot, w', each part carrying a copper jaw, U, shaped so as to clear adjacent blades; between the jaws, U, the blade to be welded is clamped and in order to ensure a good contact and rigid holding of the blade in the jaws, a clamping device is preferably arranged in addition to that provided by the spring of

~~the jaw holders~~ the two branches of the jaw holder.

According to one form, links, 83, are pivoted at 84, to one branch of the jaw holder, while short cross links, 85, connect the links, 83, to the other branch, to which they are pivoted at 86. The long links, 83, are curved as shown and are connected at their non-pivoted ends by the cross piece, 87, to which pressure to clamp the blade is applied in the direction of the arrow (see figure 19) by means of the cam, 88, and hand lever, 89, both of which are secured to a common axle rotatably mounted on any convenient pillar, 90, or the like. A spring, such as 91, serves to return the links when the blade is released.

A modification of the clamping device just described is shown in figures 21 and 22, parts corresponding to the previous modification being denoted by the same reference symbols. The links, 83, in this modified form are curved in a contrary direction to those of figures 19 and 20 and their ends are united by an armature, 92, adapted to be attracted by one or more electromagnets, 93, supported in any convenient manner on a bracket or the like secured to the crosshead, 2. The energising current to the magnets may, if desired, be switched on and off automatically.

In the case where blades are to be welded to a turbine ring, the arrangement of parts is essentially the same as that already described with the exception that the ring encircles the welding head.

It will be seen that certain parts of the machine are not completely automatic in their operation but these parts may be readily made so if the additional complication involved is not considered undesirable.

Although the machine has been described with a

slotting head attachment, it will be obvious that in order to carry into effect other of the methods described in the first part of the invention, means for drilling, graded circular cutters or other devices provided with the suitable adjustments required for carrying out the necessary mechanical operations may be substituted.

Having now described my invention what I claim as new and desire to secure by Letters Patent is:-

1. Process for the attachment of turbine blades to their carriers, consisting in so adjusting the periphery of the volume of metal in the carrier in the neighbourhood of the point of attachment by limiting the cross sectional area available for the conduction of heat therefrom, that on heating locally, said blade and said carrier rise to approximately the same temperature and welding the blades to said carriers so prepared, as set forth.

2. Process for the attachment of turbine blades to their carriers, consisting in so adjustably the volume of metal in the carrier in the neighbourhood of the point of attachment by limiting the cross sectional area available for the conduction of heat therefrom, that on heating locally, said blade and said carrier rise to approximately the same temperature and electrically welding the blades to said carriers so prepared, as set forth.

2. Process for the attachment of turbine blades to their carriers, consisting in so removing metal from the periphery of the carrier in the neighbourhood of the point of attachment that on heating locally said blade and said carrier rise to approximately the same temperature and electrically welding the blades to said carriers so prepared, as set forth.

3. Process for the attachment of turbine blades to their carriers, consisting in so grooving the periphery of the carrier in the neighbourhood of the point of attachment that on heat-

ing locally, said blade and said carrier rise to ap-
Oct. 10,1905 proximately the same temperature and ~~electrically~~

F. I. Allen.

Commissioner of Patents.

A new oath should be filed in accordance with the requirements of Rule 46. See ex parte Levenstein & Maef, 110 O.G., 1726.

Division is required in this case under Rule 41, since claims 1 to 4, inclusive, are drawn to a process; claims 5 to 10, inclusive, are drawn to an article; and claims 11 to 21, inclusive, are drawn to a machine.

Action on the merits will accordingly be deferred until applicant limits his claims to a single invention.

Sebastian Ziani de Ferranti,

c/o Spear, Middleton, Donaldson & Spear,

Washington, D. C.

Please find below a communication from the EXAMINER in charge of your application for Process and Apparatus for Electrically Welding Turbine Blades to their Carrying Elements, filed May 14, 1904, Serial No. 208,034.

F. I. Allen

Commissioner of Patents.

Responding to amendment filed September 27, 1904:

Claim 1 is rejected on Parry, 255,329, March 21, 1882, (Class 78, sub 92). This patent shows in Figs. 6 and 7 the application of applicant's principle to the construction of a locomotive frame. To apply this idea to turbine construction is not a matter of invention. This claim is also rejected as functional as the clause commencing "consisting," practically sets forth only the result desired to be attained, viz, uniform heating, instead of the means employed.

Claim 2 is similarly rejected. Further this claim is substantially the same as claim 1 and involves an aggregation for the reason that the particular method of welding, viz, electrically, has no more than its ordinary function in this relation.

Claims 3 and 4 are rejected on Parry. As in claim 2 the inclusion of electric welding involves an aggregation and further constitutes an unnecessary limitation.

Claims 5 and 6 are rejected on the British patent to Roworth, 25,086, of 1893, which shows electrically welded blades. They are also rejected as unpatentable over the German patent to Harle, 143,960, of 1900, which shows riveted blades and the U. S. patent to Elliott, 775,108, Nov. 15, 1904, which shows the blades bolted on.

Claims 7 to 10 are rejected on the references for claims 5 and 6 in view of Parry cited. These claims and claim 6 are objectionable in form as they define the article by the method of making. See Riedon v. Medart, 71 O.G., 751 and ex parte Painter, 57 O.G., 999. The fact that the article must needs be defined by the method of making in order to show novelty, would indicate that if any, only one inventive idea was involved and that was in the process.

S. Z. DE FERRANTI'S U.S. APPLICATION, No. 208,034.

Process & Apparatus for Electrically Welding Turbine Blades &c.

To the Commissioner of Patents:

The following is submitted in Reply to the Official Letter of January 10th, 1905. and to be considered in connection with the explanatory sketches hereto attached.

Applicant believes that the U. S. Patent to Parry, No. 255,329, figures 6 and 7, has little or no relevancy to applicant's invention and does not justify the Examiner in rejecting certain of applicant's claims.

The welding of turbine blades to their carriers is an operation of very considerable difficulty and delicacy by reason especially of (1) the great disproportion in size between the blade and carrier and (2) the close juxtaposition of the blades. The first condition renders it difficult to bring the welding points of the two elements to the proper temperature simultaneously without burning the blade; the second condition necessitates a very accurate concentration of heat at the welding point so as to avoid damage to the blades already fixed at a given moment.

The difficulties mentioned do not occur in the manufacture of a locomotive frame; it is to be noted that the portion, B, of the frame is quite comparable in magnitude with the various portions, D, both being of the same thickness and considerable masses of metal, and no difficulty whatever occurs owing to the close juxtaposition of the parts, D. The recesses between the projections, d, in the part, B, of the frame play no part whatever in the actual welding

operation; it will be seen that they are made alternately deep and shallow for the evident purpose of producing the desired contour of the frame. The parts, d, can be easily heated in the smith's fire in turn one after the other, there being ample space between the parts, d, to enable the heating of each part, d, to be effected without detriment to the neighbouring parts, d. It is thought that the figures in question disclose very little which a smith could not accomplish without special instructions; the only new point so far as the smith is concerned being the rounding of the butting portions (see figure 8). That this is the essential novelty of the invention and not the recesses on the part, 8, is clearly shown in the description and particularly in claim 2. It is thought that the recesses in question are purely accidental and play no useful part whatever in the actual process of welding. A sketch is submitted herewith of a locomotive frame in which the recesses between the parts d are replaced by projections; applicant confidently submits that the welding process would not suffer in any way by such substitution so long as the essential rounding winding of the parts d is maintained.

The logical outcome of the Examiner's contention as to disclosure is that a skilled workman, if given a turbine wheel and a set of loose blades could set to work and weld the blades in place without further assistance than the information given in Parry's specification. If the Examiner will put

himself in the workman's place, he will see that success under such circumstances would be little short of miraculous. How, for instance, would it be possible to heat the wheel at the welding point without burning off the blades already in place?

In point of fact, the peculiar conditions which render the welding of turbine blades in place a difficult operation do not exist in the manufacture of a coarse article such as a locomotive frame; they, therefore, were not discussed in Parry's specification and a fortiori no means were disclosed for overcoming them.

In view of the above remarks it is thought that the Examiner's further contention as to the words "electric welding" in claim 2 being an unnecessary limitation is also unsupportable. It is possible, though improbable, that having prepared the blade carriers as described by applicant, it would be possible to heat the welding points by some form of hot blast or the like; applicant, therefore, in claim 1, claimed welding broadly since he believes no one has yet succeeded in producing a bladed carrier with the blades secured in place solely by a butt weld of the type in question and he is entitled to a broad scope of protection. If, however, claim 1 was declared void for any season, claim 2 for "electrical welding" would still be good since actual success has attended this process, the elctrical welding having the specially advantageous property of definitely localising the heat. It will of course be obvious

1200

to the Examiner that the expression "electric welding" is used not in the sense of producing the required heat by playing upon the welding point with an electric arc but by means of the high resistance offered to the passage of electric current past the welding point..

Claims 5 and 6 are re-submitted and the Examiner is requested to point out the relevancy of the German patent to Harlé, No. 143,960 and the U. S. patent to Elliott, No. 775,108. It is not seen in what sense a turbine wheel having blades welded on is anticipated by wheels having blades riveted or bolted on. The welded article is a distinct improvement qua article and approaches closely the ideal form in which wheel and blades are fashioned out of one block of metal.

With regard to the British patent to Raworth, No. 25086/93, each blade is electrically welded to a root-piece thus forming a unit, the separate units being then built up into a wheel rim in various ways. Probably the welding could be effected without difficulty since blade and root-piece are comparable in size and each unit can be manufactured separately thus avoiding the difficulty caused by the close juxtaposition of the blades as explained above. Moreover, Raworth's finished article is clearly inferior to applicant's, including as it does parts such as the side plates and retaining nuts which can work loose. Additional claims introducing the term "plurality of blades" are filed herewith..

Claims 7 to 10 are also re-submitted since the finding in ex parte Painter, 57 O.G., 999, includes the following:-

"A claim for an article of manufacture should not as a rule be defined by the process of producing it; but when an article of manufacture cannot be properly defined except by reference to the process of producing it, a case is presented which constitutes a proper exception to the rule."

It is submitted that the present case is such a "proper exception"; applicant believes himself the first to produce a turbine element having the blades directly secured in place by a butt weld. Such a turbine element is an advance on anything hitherto brought out and protection should not be refused merely on account of limitations in the English and American languages. If an accepted word existed for a turbine element with butt welded blades, a claim for such element would be allowed as a new article, as such a word does not exist, applicant contends that the only course left open is to define the article by the method of manufacture.

Reconsideration of the case is respectfully solicited.

1202

Please insert the following additional claims:-

11- As a new article of manufacture, a bladed turbine element having a plurality of closely spaced blades attached to the periphery of said carrier by direct butt welds.

Canceled Oct.10,1905

12- As a new article of manufacture, a turbine carrier the rim of which is formed of circumferentially continuous metal together with a plurality of closely spaced blades attached to said continuous portion by direct butt welds.

13- As a new article of manufacture, a turbine carrier having circumferential peripheral grooves with intervening projections together with a plurality of closely spaced blades, each blade being attached to at least two of said projections by direct butt welds.

In claims 1 and 2 line 4 after "attachment" insert- by limiting the cross sectional area available for the conduction of heat therefrom.

Respectfully,

S. Z. de Ferranti,

AEW

DEPARTMENT OF THE INTERIOR

Serial No. 208034

UNITED STATES PATENT OFFICE

WASHINGTON D.C., August 5, 1905.

MAILED * * *

Sebastian Z. de Ferranti,

C/o Spear, Middleton, Donaldson & Spear,

Washington, D. C.

Please find below a communication from the EXAMINER in charge of your *application of* #208,034, filed May 14, 1904, for "Process & Apparatus for Electrically Welding Turbine Blades to their Carrying Elements".

E.I.Allen.

Commissioner of Patents.

Responding to amendment filed May 23, 1905.

The patent to Perry is waived as a reference. Claims 1, 2, 3 and 4 are rejected as presenting nothing patentable over Swedish patent to Jottrand, #17,093, March 19, 1903, (78-94). This patent discloses, in figures 3 and 4, the idea of reducing the cross-section of the heavier piece of metal in order to secure uniform heating at the welding point. Claim 2 is still considered unpatentable over claim 1, and claim 3 is the same in effect as claim 2.

Claims 5, 6, 11 and 12 are required to be divided out of the case, as the article could be produced by a process other than that recited in claims 1 to 4 (ex parte Erdman, 93 O.G., 2531).

The objection as to defining by the term "welding" in claims 7, 9 and 10 is withdrawn, but such objection relative to electric welding still holds as regards claim 8, for the reason that the term "electrically" imports no characteristic of the article, and has to do simply with the manner of making.

Claims 7, 8, 9, 10 and 13 are rejected as unpatentable over DeLaval, #522,066, June 26, 1894, (121. Rotary Impact, Axial Flow). This patent shows the turbine body with integral blades. The same turbine with a welded connection for the blades instead of an integral one is not considered patentable, for the reason that, except as to the manner of making, the two articles are the same, and if the weld is a good one the blade and the body are integral.

Process and Apparatus for

Electrically Welding Turbine

Blades to their Carrying Elements.

Filed May 14, 1904.

#208034.

To the Commissioner of Patents:

Please amend the above entitled case as follows:-

In title erase the words "and Apparatus".

Cancel claim 2.

Claim 3, line 6, cancel "electrically" and renumber to 2.

Claim 4, line 5, cancel "electrically" and renumber to 3.

Insert as a new claim:-

4. Process for the attachment of turbine blades to their carriers, consisting in forming circumferential grooves with intervening rings of metal around the carrier thereby limiting the cross sectional area available for the conduction of heat from the point of attachment so that on heating locally, said blade and said carrier rise to approximately the same temperature and welding the blades to said carriers so prepared, as set forth.-

C
Sub. D.
Oct. 18-06

Claim 7; renumber to 5 and line 4 cancel "the" between "retard" and "flow."

Cancel claim 8.

Claim 9; renumber to 6 and line 4 cancel "the" between "retard" and "flow".

Claim 10; renumber to 7 and line 4 cancel "the" between "retard" and "flow".

Insert as a new claim:-

Subs. D. Oct. 18-06

8. A blade turbine element, comprising in combination a blade carrying element having circumferential grooves with intervening projecting rings of metal formed threron and blades welded across the edges of at least two of said projecting rings, as set forth.-

Cancel claims 11 to 13 inclusive.

With regard to the Examiner's rejection of the claims for the article on the U. S. Patent No. 522066, Laval, it is thought that the turbine wheel shown in the specification is purely diagrammatic and was purposely shown so by the patent attorney who drew the specification, since the method of attachment of the blades to the wheel formed no part whatever of the invention concerned. Applicant submits that this specification is not a fair disclosure of a wheel having blades integral therewith. Moreover it is thought that there are many forms of bladed turbine wheels and the like which it would be quite impossible to produce out of a solid block of metal, such for instance, as a turbine wheel having comparatively long blades very closely spaced with regard to one another. Such a wheel could, however, be readily produced by applicant's process.

Taking the four claims for the article now on file, it will be seen that these call specifically for a turbine element in which, (1) the volume of metal has been adjusted in the neighborhood of the point of attachment of the blade; (2) metal has been removed in the neighborhood of the point of attachment; (3 & 4) grooves have been cut; and moreover, welded blades are called for in each case. All these features are new over Laval, in which no metal has been removed, no grooves have been cut and the blades are not welded on.

It therefore appears that a different article must necessarily have been produced. A turbine wheel or the like having blades welded thereto is new in the art, and it appears that whether it has advantages or disadvantages as compared with the existing turbine wheels, it is, nevertheless, a substantially different article to one in which the blades are integral with the wheel or welded or bolted thereto.

Applicant respectfully submits that the Examiner has himself admitted this by withdrawing his objection to the use of the word "welding" in defining the article.

As regards the citation of the Swedish patent to Jottrand #17093 of March 19, 1903, applicant submits the following statement:-

The present application was filed in America on May 14, 1904, and the British equivalent application #11921, 1903, was filed in England on May 25, 1903, as proved by the oath. Consequently it is believed that under the terms of the International Convention, to which Great Britain and America are parties, no publication subsequent to the date of filing in England, viz., May 25, 1903, affords grounds for the rejection of claims in the American application. Now the Swedish Patent to Jottrand #17093, was not published until Feb. 13, 1904, as shown by the note "Offentliggjord dem 13 Februari 1904" at the foot of page 2 of the Swedish specification; it istherefore thought that the citation of the Swedish specification is not in order on the part of the U. S. Office in the present instance.

Respectfully,
S. Z. de Ferranti,

Care Spear, Middleton, Donaldson & Spear,

Washington, D. C.

Please find below a communication from the EXAMINER in charge of ~~the~~ your application of

for Process and Apparatus for Electrically Welding Turbine Blades to their Carrying Elements, filed May 14, 1904, Ser. No. 208,034.

F. I. Allen
Commissioner of Patents.

In response to amendment filed October 11, 1905;

Requirement for a new oath in accordance with decision of Levenstein & Naef, referred to, is repeated.

Claims 4 and 8, it is thought, may be allowed. The examiner believes that an invention was made in the production of the article defined in claim 8.. Whether the invention is in the process or the article may be somewhat doubtful and for that reason it is believed to be proper to allow both claims in the same application.

All of the other claims are rejected in view of the references cited, and the additional reference, patent to Cowdery, 481,663, August 30, 1892, Class 76, Subclass 111. The application of the old method disclosed in Cowdery to the manufacture of a turbine wheel is thought to involve no invention.

Attention is invited to the fact that claims 5 and 6 of the original specification have not been canceled although applicant's procedure indicates that he intends to cancel them.

Pen and ink drawings are required.

S. Z. de Ferranti.

Process and Apparatus for Electrically Welding Turbine Blades to their Carrying Elements.

Filed May 14, 1904.

#208034.

To the Commissioner of Patents:

Referring to the U. S. patent to Cowdery, #481663, cited by the Examiner, applicant desires to submit the following statement.

It is thought that the method of Welding the braces to the heads of rakes disclosed by Cowdery cannot be held to be an anticipation ofapplicant's method according to U. S. patent law unless (1) a mere application, involving no ingenuity whatever, is possible of Cowdery's method to turbine work, and (2) unless the arts of rake making and turbine building are reasonably cognate.

Applicant believes that neither of these conditions in point of fact exists. Cowdery's method of stamping out a blank with two luge which he subsequently bends at right angles is obviously inapplicable as it stands to turbine work and for this reason something more than the mere application required by law is necessary to adapt it. Thus the "cresent-moon" section of a turbine blade made it impracticable, after the broad principle had been discovered, to form projections of similar section on the turbine wheel in the manner disclosed by Cowdery and much trial work was necessary in view of the pronounced disproportion in dimensions between turbine wheel and blades before it could be confidently stated that the methods disclosed in applicant's specification were or were not successful.

Applicant wishes especially to emphasize the fact that it is the great disproportion in dimensions between turbine wheel and blade which has occasioned the practical difficulties met with which have hitherto prevented a welded turbine element of the type in question being produced. This difficulty does not occur in the rake shown by Cowdery where the section of the braces to be welded is apparently the same as that of the base member of the head to which it is held, both parts being considerable masses of metal of no great difference in size.

Furthermore, it is thought that the arts of rake making and turbine building cannot be considered so closely allied that processes known in the one art can be considered available for use in the other. Applicant with a large practical experience in all branches of engineering, believes that no common knowledge existed at the time of his invention which would assist in the solution of the blade-welding problem, and it is thought that a very special process confined solely to such a backwater of the engineeringtrade as rake-making cannot be held to be such "common knowledge" and should not preclude the grant of a patent for improvements in an art of the importance of turbine-making.

Reconsideration of the case is respectfully solicited in view of certain of the following amendments drafted in order to connect the invention more definitely with turbine production.

Cancel claims 5 and 6 of the original specification.

Claim 1, line 3; claim 2 line3; claim 3, line 2; between "the" and "camer" insert-periphery of the-

Claim 5, line 2; claim 6 line 2; before "which" insert - the peripheral portion of-

Claim 7 line 2; after "element" insert-having its peripheral portion-

Applicant is considering the question of filing a division al application.

A new oath and drawings will be filed before this case goes to issue.

Respectfully,

S. Z. de Ferranti,

Process and apparatus for Electrically welding turbine Blades to their Carrying Elements.

Filed May 14th, 1904.
208034

To the Commissioner of Patents.

With respect to the reference Cowdery of record applicant wishes to point out that there is no disclosure of his process by Cowdery; on a careful perusal of Cowdery's specification it will be evident to one skilled in the art that Cowderys method consisted in heating the parts separately to a welding heat before uniting them as in lines 55 et seq he causes "the meeting surfaces which have been heated to welding heat by the current to be brought against each other and uniting them" There is no dubiety in the language of the specification; the parts have been heated to welding heat before being brought together, so that Cowderys method presents no similarity to the applicants in which the welding current is lead across the junction of the parts to be welded. That such a method was never invented by Cowdery is evident from the passage quoted above and also to the following parts of his specification. In line 44 et seq. Cowdery intimates his intention of applying electric welding to the manufacture of his rakes. There are three kinds of welds which present themselves to his mind viz., Butt, scarf or T welds. It must be borne in mind that these joints are intended to be formed electrically and the problem which he has to solve is which joint will be preferred for his rake. He chooses the

butt or scarf weld in preference to the T weld his reason for such preference being as stated in line 59 that if T welds were formed it would be necessary to heat the whole head of the rake to the welding temperature. Had Cowdery even contemplated using the applicant's method in which the welding current is led across the junction of the parts to be welded no heating of the entire head of the rake would have been necessary and owing to the parts being of similar cross section a perfectly good weld could have been formed. In order to avoid clamping the whole head of the rake in the clamps and heating to welding heat, Cowdery forms two projecting lugs on the head and thus obviate the necessity of raising the whole of the head to the welding temperature. These lugs were clamped between the terminals of a suitable welding circuit heated to welding heat and then united to the braces which had been similarly heated.

This interpretation of Cowdery's specification, applicant submits is the only one which agrees with the language used in the specification and applicant holds that the diversity of the respective arts should not allow a strained interpretation to be put on Cowdery's specification to the detriment of an invention which has solved the problem of expeditiously attaching turbine blades to their carrying elements in an exceedingly affective manner. Furthermore the problem before Cowdery was that of attaching two parts by electric welding which were situated remote from one another; in fact an ordinary piece of electric welding which would present little or no difficulty to any person once the idea of electric welding was

known as the heat capacities of the parts were practically equal. In the applicants invention however the difficulties of welding efficiently masses of metal which differ in proportion to their heat capacities as much as 10,000 and over to 1 would in no whit be minimised by a perusal of Cowdery's specification while in addition to such difficulty a further one is presented by the exceedingly close juxtaposition of the blades. It will be evident that this latter difficulty is entirely overcome by the method which the applicant has shown in his specification, i.e., by limiting the cross sectional area at the point of attachment. This method allows the heat to be concentrated or localised at the welding point and so prevent heating of an unnecessary large amount of metal in ~~that~~ the neighbourhood of the weld. Without any localisation of the welding parts it will be obvious that the rate of welding would be greatly decreased as the time required to heat the parts to the welding temperature would be increased owing to larger mass of metal to be heated.

The above difficulties do not occur in Cowdery's method so that his invention cannot in the applicants opinion be deemed an anticipation of the applicants invention which has solved the difficult problem of uniting turbine blades to their carrying member in an expeditious, economical and satisfactory manner.

With respect to Raworth of record applicant submits that in the specification the blades are not welded directly to their carrying element, the welding being simply mentioned as an alternative for soldering the blades to the rings and that the claims as now amended are clear of the above and other references

cited by the Examiner.

Claims 1 and 2 have been amended so as to clearly differentiate between the applicant's process and Cowdery's; claim 3 has been refiled as none of the references show "grooving the carrier in the neighbourhood of the point of attachment". The pertinency of the reference is not seen. Claims 4 and 7 as now on file have been allowed; claims 5 and 6 have been substituted for those rejected on the last official action. A reconsideration of the case is respectfully solicited on the above grounds and it is hoped that the case will soon pass to an early allowance.

Cancel all the claims and substitute the following:-

2. ~~1.~~ Process for the attachment of turbine blades equalizing the heat capacity of the welding parts by to their carriers, consisting in limiting the cross sectional area of the carrier available for conduction of heat from the point of ~~attachment~~ contact, causing blade and carrier to contact and leading welding current through the point of contact, as and for the purposes set forth.

3. ~~2.~~ Process for the attachment of turbine blades equalizing the heat capacity of the welding parts by to their carriers, consisting in removing metal from the carrier in the neighbourhood of the point of ~~attachment~~ contact, thereby limiting the cross sectional area available for conduction of heat therefrom, causing blade and carrier to contact and leading welding current through the point of contact, as and for the purposes set forth.

#208,034, filed May 14, 1904, for "Process & Apparatus for Electrically Welding Turbine Blades to their Carrying Elements".

P. I. Allen

Commissioner of Patents.

6-2611

Responding to amendment filed Oct. 18, 1906.

Claim 1, 2 and 3, which are for a process, and claims 5 and 6, which are for an article, are all rejected as being unpatentable over Cowdery, of record. Claims 5 and 6, although for an article, do not set forth and define any structure which patentably differentiates from the patent upon which these claims are rejected.

Applicant is also referred to the patent to Hunter, #690,958, Jan. 14, 1902, as further showing a process of electric welding.

Claims 4 and 7, which are old claims 4 and 8, stand allowed.

Process and apparatus for Electrically welding turbine blades to their carrying elements.
Filed May 14th, 1904
No. 208034.

To the Commissioner of Patents:-

Insert as claim 1:-

Substitute F Apr. 19. 07. a

1. Process for the attachment of blades to their carrying elements consisting in equalizing the heat capacities of the welding parts by limiting the cross sectional area of the carrier available for the conducting of heat from the point of attachment, so that on heating locally said blade and said carrier rise to approximately the same temperature and welding the blades to said carriers so prepared.

Renumber claims 1, 2, 3 and 4 as claims 2, 3, 4 and 5 respectively.

Old claim 1, now claim 2, line 2 after "in" insert "equalising the heat capacity of the welding parts by";

line 4 change "attachment" to contact

Old claim 2, now claim 3, line 2 after "in" insert "equalising the heat capacity of the welding parts by"

line 3 erase "at"

line 4 erase "tachment" and insert "contact" therefor.

Insert as claim 6.

Ba Canceled Apr. 19-07.

6. A bladed turbine element comprising in combination a blade carrying element and a plurality of blades attached thereto by welds, said welds acting to transmit working stresses between said blades and said carrying element, as set forth.

Renumber claims 5, 6 and 7 as 7, 8 and 9.

Insert as new claims:-

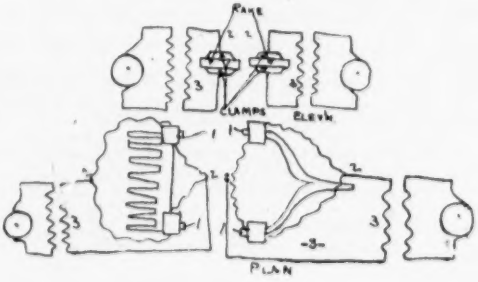
10. A welded turbine element comprising in combination a blade carrying element having a circularly disposed aggregation of depressed portions alternating with relatively raised portions and blades welded to said relatively raised portions, as set forth.

11. A bladed turbine element comprising in combination a body portion; a circularly disposed aggregation of blade carrying members proper attached to said body portion by one face and having blades welded to an opposite face together with spaces intervening between said blade carrying members, as set forth.

12. A bladed turbine element comprising in combination a blade carrying element having a plurality of raised portions with relatively depressed portions disposed on both sides of said raised portions and blades welded to said relatively raised portion, as set forth.

The Examiner is reminded that claims 5 and 9 stand allowed.

It is respectfully submitted that the amended claims are free from the reference Hunter of record who shows no "equalisation of the heat capacities of the welding parts" which is one of the essential elements of the applicants invention. Hunter arranges the heat capacities of the parts at the welding point in as great disproportion as possible so that the projections on one of his parts become a mass of molten metal before the welding operation is effected.



In the applicant's invention the temperature of the parts never rise above the welding temperature and fusion of the parts is carefully avoided.

With regard to Cowdery also of record applicant respectfully submits that as Cowdery does not disclose

one of the steps in applicants process viz., leading the welding current through the point of contact that the process set forth in the claims rejected on this reference is certainly novel.

Further when the state of the art is examined it is found that one of the great difficulties encountered in the manufacture of turbines is that of providing efficient means for attaching the blades to the carriers. One of the most usual method of attachment is by means of caulking strips which at best forms an antiquated and very unworkmanlike species of jointwithout taking into consideration the time and labour involved.

By means of the process described in his specification the applicant is able to weld blades to the carriers at the rate of 400 per hour while the strength of the weld is such as to permit them to be hammered over at right angles to the position in which they were originally welded. The process which enables blades to be attached so expeditiously and efficiently in comparison with the present cumbersome methods in the applicants opinion ought to be patentable the more especially when it is considered that the anticipating reference relates to a backwater art like rakemaking and which as will now be shown does not disclose the applicants invention.

Referring to lines 50 to 59 of Cowdery's specification and to the sketches inserted above which have been provided with reference numerals to illustrate Cowdery's method, the following statement is found.

"In electric welding the two pieces, 1, to be welded are suitably clamped in the terminals, 2, of a circuit, 3, carrying a current of large volume and of low tension and the clamps (s), 4, holding the pieces are thereupon brought together with great force bringing the meeting surfaces which have been heated to welding heat against each other and uniting them."

It will be evident that such a method does not disclose the applicant's process as there is no suggestion of leading the welding current through the point of contact.

Cowdery heats each part individually to welding heat on the attainment of which both are forced together. The welded parts of Cowdery's rake are so far apart as to present no difficulty in this connection and the weld could have been effected without the slightest difficulty in the ordinary manner.

To apply Cowdery's process to the rotor for example of a turbine of the Parsons type it would be necessary to keep a cylinder of metal some 6 ft. long say at a welding heat during the whole welding operation, which would obviously be self-damnatory.

The applicant however was the first to perceive that by equalising the heat capacities of the welding parts and leading the welding current across the point of contact thereby localising and concentrating the heat it was possible to electrically weld blades to a rotor successfully both from the practical and commercial standpoints even although the proportion of the heat capacity of the

and
roter/ blade would in ordinary circumstances amount to as much as 10,000 to 1.

Cowdery disclosed no adjustment of the heat capacity because as has been stated above the materials with which he was dealing were practically of the same size and section. Cowdery did not disclose leading the current through the points of contact; Cowdery's process was a mere case of substituting one species of welding for another and lastly the arts of rake and turbine making are not so closely allied as/ to amount to mere application. On these grounds applicant is of opinion that claims 1, 2, 3 and 4 ought to be allowed.

With regard to claims 6 and 7 applicant is unable to perceive how a claim for a bladed turbine element is rejected on a rake.

Claim 6 calls for "a blade carrying element having depressed portions on its peripheral area with intervening portions raised relatively to said depressed portions" This claim calls for a plurality of raised portions alternating with depressed portions which is certainly not disclosed in Cowdery's specification. Claim 8 calls for "blade carrying members proper attached to the body portion by one face and having blades welded to an opposite face". Applicant is unable to understand the ~~pertinacity~~ pertinency of the reference in respect to this claim.

As the article of manufacture claimed is novel in addition to being stronger and able to be more expeditiously manufactured than those at present on the market it is thought that the claims at present on file ought to be allowed.

If the Examiner persists in his rejection of the claims applicant would esteem it a favour if he would do so finally in order that the case may be taken to

appeal.

UNITED STATES PATENT OFFICE

AEW

WASHINGTON D.C., March 11, 1907.

MAILED

Sebastian Z. de Ferranti,

C/o Spear, Middleton, Donaldson & Spear,

Washington, D. C.

Please find below a communication from the ***EXAMINER*** *in charge of your application of*

#208,034, filed May 14, 1904, for "Process & Apparatus for Electrically Welding Turbine Blades to Their Carrying Elements".

F. I. Allen

Commissioner of Patents.

Responding to amendment filed Feb. 16, 1907.

Claim 1 is rejected on Cowdery, of record. The claim amounts in substance to the process of attaching one set of members (the "braces B) of Cowdery to a second member (the head A of the rake in the same patent), which consists in equalizing the heat capacities of the welding parts by limiting the cross-sectional area of the second member available for the conducting of heat from the point of attachment, so that on heating locally said first member and said second member they rise to approximately the same temperature, and welding the blades to said second member so prepared. Would it not be well for applicant to place a comma after "temperature" in line 7 of this claim?

Applicant in his argument states, on page 4 of the amendment filed Feb. 16, 1907, that "It will be evident that such a method does not disclose the applicant's process, as there is no suggestion of leading the welding current through the point of contact". Applicant is referred to lines 39 to 70 of the Cowdery patent, above referred to. The examiner considers that the said patent discloses the employment of the "process of welding ordinarily employed", which is substantially the same process as that described in the patent to Eyre, #585,160, June 22, 1897, (78-82x), (see page 1 of the specification, lines 27 to 41). It is further considered that the Cowdery patent also discloses

de Ferranti, #208,034 -- 2.

that it is old to weld "by equalizing the heat capacities of the welding parts and leading the welding current across the point of contact" which applicant in his argument asserts that he is the first to perceive (see lines 39 to 70 of the Cowdery patent, above referred to, and especially the subject-matter of lines 66 to 70). Hunter, of record, also shows the welding together of two members by forming projecting portions and sending the current through and heating locally in the vicinity of the projecting portions.

Claims 2, 3 and 4 are rejected on the references and for the reasons given in the rejection of claim 1.

Claims 6, 7 and 8 are rejected on Cowdery. While these claims are drawn to be for a "turbine element", they define no structure (for example, taking claim 7) which is anything more than an element having in combination a depressed portion (for if there are projecting portions there are depressed portions, and vice versa) on the outer portion with intervening portions raised relatively to said depressed portions, and members welded to said relatively raised portions, as set forth. Such a structure is clearly unpatentable over Cowdery.

Claims 5 and 9 stand allowed.

Claim 10 is broad enough to read on figures 1, 1^a, 2, 5 and 6, and is unpatentable in view of Cowdery.

Claim 11 is for a different species from that for which claim 9 has been allowed, and is not readable upon the same structure which claim 9 represents. Therefore no action on the merits of this claim has been make, and the claim is required to be canceled. Applicant is referred to ex parte Cook, 51 O.G., 1620.

Claim 12 is rejected as claim 10.

Process and Apparatus for Electrically Welding Turbine Blades to their Carrying Elements.

Filed May 14, 1904.

#208,034

To the Commissioner of Patents:

Erase all claims excepting 5 and 9 and insert:-

Sub P'

1- The method of attaching turbine blades to their carrier of relatively great mass, which consists in adjusting the heat capacity of localized areas of the carrier at the point of attachment, by ~~limiting the heat conduction between~~ partially isolating these areas from the remainder of the carrier ~~and the relatively great mass~~, so that a welding temperature may be reached notwithstanding the cooling effect of the mass of thecarrier, and passing electric heating current directly through the carrier, and by way of clamps through the blades to weld the blades in succession ~~successively~~ to the carrier, substantially as described.

per J.

F

per I

2- The method of attaching turbine blades to their rotor carrying element ~~and maintaining the balance of the rotor~~ consisting the equalizing the heat capacities of the welding parts by limiting the conducting areas of the carrier, at the points of blade attachment, symmetrically in relation to the axis of rotation of the rotor, and enclosing the blade between clamps so that on heating locally by the electric current the blade and carrier rise to approximately the same temperature and welding the blades to the carriers so prepared. -

per I

per J.

Insert H3

At the end of the specification insert:-

F'

The elctric heating current is passed directly through the carrier and by way of clamps through the blades. -

There is a clear difference between the method set forth in the above claim and that of Cowdery. In Cowdery the purpose is to prevent heating up and burning of the body of the rake. In de Ferranti's case, on the contrary, the purpose is to provide a way by which to oppose the cooling tendency, due to the heat conducting capacity of the larger mass of metal to which the comparatively small blades are to be welded.

Cowdery's problem was to prevent burning up the body of the rake. de Ferranti's problem was to get sufficient heat at the attaching points of the blades, notwithstanding the tendency of the heat to be dissipated throughout the larger mass.

Cowdery in his method provided clamps for holding the body of the rake to keep it out of the heating circuit.

Applicant does not employ clamps for the carrier, but passes the current directly through the larger mass of metal, and he limits the conduction of heat between the attaching point or area for the blade and said larger mass so that a sufficiently high temperature for welding purposes will be secured at the point of contact.

It is submitted that the problem to be dealt with by applicant arose because of the requirements and conditions of this particular art, i.e. that of making bladed carriers for turbines and although applicant isto be charged with the knowledge of the Cowdery patent it is not thought that this knowledge would suggest the present method.

Applicant was not facing the problem of preventing the carrier from burning, as its comparatively great mass in relation to the blades rendered this impossible, but he had to provide means of preventing the rapid cooling tendency of the larger mass from dissipating the heat away from the attaching points or areas and thus preventing a good weld.

Furthermore, it has been the practice heretofore in attaching blades to rotors, to calk them in place, or to hold them by filling pieces together with calking. As a result of this method, and owing to inequalities, it has been necessary to balance the rotors by boring cavities therein at various places and filling the same with lead, a process requiring skilled labor and the expenditure of considerable time. With my present process in which the limited conducting areas of the carrier are disposed symmetrically in relation to the axis of rotation, and in which the blades are welded to these symmetrically disposed areas, the rotor as is comes from the welding process requires no special balancing. Applicant has thus produced an advance in the art of making rotors for turbines and one not suggested in any way by the Cowdery patent. If any advantage results from applicant's process in this specific art, it is thought he should have protection on the advance which he has made.

Applicant reserves the right to file a divisional application for the article.

Respectfully,

S. Z. de Ferranti,

E. B. Moore.

Commissioner of Patents.

6—2632

Responding toamendment filed April 19, 1907.

Claims 1 and 2 are rejected as being unpatentable over Cowdery, of record. and Eyre, also of record, in view of Moxham, #496,890, May 19, 1893, (219-10). In claim 2 applicant has included as an element "maintaining the balance of the rotor"; this phrasemerely states what is the result of the process, rather than aiding in defining the process.

Claims 3 and 4 stand allowed.

Amendment

G. Z. de Ferranti Filed May 9, 1908
Process and apparatus for electrically welding turbine blades to their carrying elements.
Filed May 14th 1904.
Serial No. 208034.

To the Commissioner of Patents:

Erase "and apparatus" from the title of the specification.

Insert at the end of the specification.

"By means of my invention it will be seen that the blades are attached to their carrying elements in an expeditious and efficient manner while in the case of rotors a still further advantage is obtained over the methods of blading commonly employed inasmuch as it properly carried out the attachment of the blades by electric welding introduces no change of symmetry with respect to the axis of rotation and consequently dispenses with the tedious operation of balancing otherwise rendered necessary."

With respect to the rejection by the Examiner of claims 1and 2. applicant respectfully submits the following in support of their patentability. First with regard to Cowdery's specification applicant would point out that Cowdery's specification should be considered totally apart from any knowledge subsequently acquired from applicant's specification and the test applied whether a skilled workman with Cowdery's specification as the state of knowledge in the art could evolve the applicant's process without exercise of the inventive faculties. What information then would such a person obtain from Cowdery's specification? Would it be sufficient to teach the public how to perform the applicants

process? In the first place, the problems in question are entirely different. Cowdery seeks to avoid the occurrence of a high temperature for fear of burning the parts concerned; applicant on the other hand and in direct opposition to this seeks to secure a temperature in the carrier high enough for welding. Cowdery, in other words gets too much heat; applicant cannot get enough in the carrier or if he can runs the risk of burning the small blades. Applicant's solution of the problem consists in two parts:- (a) partially isolating a part of the carrier by grooves and the like to prevent rapid conduction of heat away from the welding point by limiting the available cross sectional area and (b) artificially increasing the mass of the blade being welded by clamping it between copper jaws of large heat capacity and leading the current not directly to the blade but by way of the clamps. There is thus a contrast in the manner of treating the carrier and the blade; current is led directly to the partially isolated portion of the carrier but only indirectly to the blade by way of the heavy copper clamps which enclose the whole of the blade with the exception of the extreme tip. The carrier is thus compelled to rise to the welding temperature while the blade is prevented from burning. Or put differently the very large mass of the carrier and the very small mass of the blade rise in temperature at approximately the same rate. To secure this result has been ~~the~~ Applicant's outstanding difficulty throughout and it is only achieved by a differential treatment of the parts to be welded.

Cowdery's specification is ambiguous on many

points but there is clearly no suggestion of the differential mode of leading current to the welding point now emphasised in applicant's claim 1. Neither is there in Moxham of record. In each case this is explained by the fact that neither Cowdery nor Moxham was contemplating the welding together of two parts differing to any considerable extent as regards mass and heat capacity while applicant on the contrary deals directly with such a case.

Turning to claim 2, the point is made of maintaining the balance of the rotor by cutting the grooves, recesses or the like "symmetrically in relative to the axis of rotation of the rotor". It appears indisputable that no such suggestion is made by either Cowdery of Maxham.

For the above reasons it is requested that claims 1 and 2 as they now stand may be reconsidered.

Respectfully,

S. Z. de Ferranti,

DEPARTMENT OF THE INTERIOR

UNITED STATES PATENT OFFICE

Serial No. 208034

WASHINGTON June 5, 1908.

MAILED " " "

Sebastian Z. de Ferranti,

C/o Spear, Middleton, Donaldson & Spear,

Washington, D. C.

Please find below a communication from the EXAMINER in charge of your application of

#208,034, filed May 14, 1904, for "process for Electrically Welding Turbine Blades to their Carrying Elements".

E. B. Moore.

Commissioner of Patents.

Responding to amendment filed May 9, 1908.

The action with respect to claims 1 and 2 is believed to be correct, and is adhered to. To the formation of the carrier in a certain way it is considered immaterial/ whether the electric heating means is connected directly to the carrier, and to the blades or by some other means, by clamps/, and therefore these elements, it is considered, do not aid in conferring patentability to the claims. It is true that Cowdery, of record seeks to avoid the occurrence of high temperature, for fear of burning the parts concerned, but it is considered that he does substantially the same thing that applicant does, and for the same purpose, only stated in a different way. Cowdery makes one part smaller at a certain portion, so that he can heat the reduced part to a welding heat in the same time that the other part to be connected thereto is heated to a welding heat, and in both the case of Cowdery and of applicant the same difficulty is encountered, namely, heating a relatively large part to a welding heat at a certain point in the same time that a smaller part is heated to the same temperature. Cowdery has solved the problem how to do this.

Attention is called to Rule 50, which requires that the drawings show every feature of the invention covered by the claims. There is nothing in the drawings of this application which shows the clamping means or the connections between the electric heating means and the elements to be welded.

Paper No. 18
Amendment H

Room 382.
S. Z. de Ferranti
Bladed Turbine Element and Process for the manufacture thereof.
Filed May 14th, 1904.
Serial No. 208034.

To the Commissioner of Patents.

Reply to Office action of June 5th, 1908.

Sir,

Reply to Official action of June 5th 1908.

Change title to "Bladed turbine element and process for the manufacture thereof".

Page 3, at end of line 8, insert the word "and", and between lines 8 and 9 insert as a new line:-

H' "Figs. 12 and 13 show a form of clamp and a diagram of the electrical connections".

Page 5, between lines 17 and 18 insert as a new paragraph:-

H2 "In every case it will be seen that those portions of the carrier to which the blades are to be welded are partially isolated from the body of the carrier bu slots, holes and so forth so as to limit the cross-sectional area available for the conduction of heat, and so compel the carrier to rise to the welding temperature. On the other hand to prevent the blades being burnt away, their mass is artificially increased by holding them between clamps or jaws of high heat conductive material such as copper.

Thus referring to figures 12 and 13, the jaw holder 63, is separated into two branches by means of the slot, 64, each branch carrying a copper jaw, 65, shaped so as to clear adjacent blades. Between

the jaws, 65, the blade to be welded is clamped, so as to leave the tip only exposed as seen in figure 13, and in order to ensure a good contact and rigid holding of the blade in the jaws, a clamping device is preferably arranged in addition to that provided by the spring of the two branches of the jawholder.

According to the form shown links, 66, are pivoted at 67, to one branch of the jaw holder, while short cross links, 68, connect the links, 66, to the other branch to which they are pivoted at 69. The long links, 66, are curved as shown, and are connected at their non-pivoted ends by the cross-piece, 70, to which pressure to clamp the blade is applied in thedirection of the arrow (see figure 13) by means of the cam, 71, and the hand lever, 72, both of which are secured to a common axle rotatably mounted on any convenient support, 73. A spring such as 74, serves to return the links when the blade is released.

The necessary electrical connections to affect the welding are shown diagrammatically on figure 13, in which G, represents an appropriate source of alternating current, and T, a transformer. It will be seen that while the lead, $\underline{t}'$, may be connected directly to the carrier $\underline{a}$, as in the example shown, it is necessary on the other hand that current to the blade, $\underline{d}$, should be conveyed indirectly by way of the jaw holder, 63, and lead, $\underline{t}^2$."

1228 ✓ .Insert the following as new claims:-

3. Process for the attachment of turbine blades to their carriers consisting in partially isolating those portions of the carrier in the neighbourhood of the points of attachment of the blades, to limit the cross-sectional area available for the conduction of heat therefrom; artificially increasing the volume of the blades by contacting them with metal masses of high heat conductive capacity and finally welding together the carriers and blades so prepared.

H3

~~4.~~ Process for the attachment of turbine blades to their carriers consisting in partially isolating those portions of the carrier in the neighbourhood of the points of attachment of the blades, to limit the cross-sectional area available for the conduction of heat therefrom; artificially increasing the volume of the blades by contacting them with metal masses of high heat conductive capacity, and finally welding together the carriers and blades so prepared by passing electric current to the blades by way of said metal masses.

per I.

~~5.~~ 4. Process for the attachment of turbine blades to their carriers consisting in partially isolating those portions of the carrier in the neighbourhood of the points of ~~the~~ attachment of the blades, to limit the cross-sectional area available for the conduction of heat therefrom; artificially increasing the volume of the blades by clamping them between metal masses of high heat conductive capacity so that the tip of the blade only is exposed and finally welding together the carriers and blades so prepared.

per J.

Change claims Nos. 3 and 4, to 6 and 7 respectively, and insert the following as new claims:-

7. ~~6.~~ A bladed turbine element having partially isolated portions and blades welded thereto.

per J.

H⁴ 8. ~~9.~~ A bladed turbine element comprising in combination a blade-carrying element having circumferential grooves with intervening projecting rings of metal formed thereon, and uniformly spaced blades welded to said projecting rings.

9. ~~10.~~ A bladed turbine element comprising in combination a blade-carrying element having a portion of uniform curvature and blades welded thereto, said blades being disposed at equal distances from the centre of said uniform curvature.

10. ~~11.~~ A bladed turbine element comprising in combination a blade-carrying element having an axis of symmetry and blades welded thereto in positions symmetrically disposed about said axis.

Insert I'

Attention is respectfully drawn to the fact that the present application was originally filed in combination with application Serial No. 236048, which has since matured into patent No. 911222. Applicant therefore respectfully requests permission to reinsert the figures and corresponding description of the blade clamp originally on file, but cut out subsequently when dividing the application.

A new sheet of drawings is filed herewith to be made of record. The process claims which at present stand rejected, applicant proposes to appeal in due course and takes no further action in relation

to them for the present.

With regard to the three new process claims filed herewith, applicant believes that these have points of novelty over anything shown in the reference.

To sum up the position shortly once again, applicant has met with two difficulties in welding turbine blades to their carrying elements:-

(a) On account of the large volume of the carrier, the heat is conducted away from the welding spot so quickly that the required temperature cannot be reached, while

(b) the small mass of metal in the blades renders them peculiarly liable to be overheated and burnt.

These difficulties are overcome respectively by partially isolating appropriate portions of the carrier to ensure the temperature of these parts rising to the required degree, while on the other hand artificially increasing the mass of the blades by putting them into good electrical contact with suitable masses of copper or other high conductive material, the current being led to the blade by way of these metal masses.

This artificial increas of the mass of the blades is a vital and essential part of applicant's process since in this way alone can the delicate blades be kept sufficiently cool. The blade carrier and the blades have thus to be treated differentially. The carrier must be assisted to rise to the required welding temperature, while the blade must be assisted to keep sufficiently cool. It is

believed that this opposite differential treatment of carrier and blade for a specific purpose is not to be found in any of the references cited.

A careful reconsideration of the case as amended is respectfully solicited.

Respectfully,

S. A. de Ferranti

By

Spear Middleton, Donaldson & Spear

Attorneys.

Serial No. 208034
Filed May 14th, 1904
Process for electrially welding turbine blades to their carrying elements.

To the Commissioner of Patents.

Sir,

This amendment is in reply to the Official letter of May 24th, 1909. A new oath is filed herewith.

not entd
See Examiners letters
also Amend F.

Page 2, line 31,

Page 3, lines 2 and 7,

Change "scrap" to "partial"

Insert figures 12 and 13 filed with the last amendment.

Page 2, line 20, insert "Figure 4a shows an elevation of the carrier shown in figure 4".

Claim 1, line 9, change "successively " into "in succession".

Claim 2, lines 2 and 3 erase " and maintaining the balance of the rotary".

Claim 7, line 5, erase "at least"

line 5, erase "two" and insert therefor "certain".

With regard to claims 1, 3 and 5 which the Examiner has objected to upon Cowderey, Eyre and Moxhan, the applicant would very respectfully point out that none of these specifications disclose the applicant's process.

Taking for example Cowderey's specification, it appears to the applicant that a different construction would be given to the language used by the Cowderey specification by persons who had not seen the applicant's process, and by persons who were familiar therewith. The article which Cowderey proposes to manufacture is one involving no special difficulties with regard to welding, as it is obvious to anyone skilled in the art that by forming slight projections on the back of the rake for welding the fork thereto the necessity of heating up the whole of the head of the rake would be dispensed with. Cowderey in fact wished to protect the points of his rake from the deleterious action which would result from being heated up to the welding temperature; he consequently resorts to a method which is very well understood in the art, and by making a slight projection on the back of the rake he welds the fork thereto.

In this specification the problem is not presented of welding an article like a turbine blade on to a blade-carrying element, the blade-carrying elementsbeing generally of much greater mass than the turbine blade, and it is respectfully submitted that Cowderey's specification would not materially assist any person who had the above problem to solve.

What the applicant does is to partially isolate the parts of the carrier upon which the blades are to be welded, and in addition thereto hold the blade in such a way as to artificially increase its heat capacity, or in other words, the heat capacity of the smaller mass is augmented while the heat capacity at the point where the blade is welded on

to the larger mass is reduced so as to allow the welding operation to be performed as efficiently as possible. Cowderey's specification does certainly not disclose a method of increasing the smaller part to be welded, and unless an exceedingly strained interpretation can be put upon the language which he uses, in the applicant's opinion he does not disclose a method of welding together parts of a dissimilar mass by reducing the heat capacity of the latter. Cowderey's process is simply one which would be chosen for convenience by blacksmith if he has faced the problem of welding a fork to the head of a rake, such as Cowderey wishes to manufacture by employing one of the very well known methods in the art. The applicant, however, had a much more difficult problem to solve, and not only were the masses so very dissimilar but the difficulties for obtaining a good weld were infinitely more than in the case with Cowderey's specification.

With regard to Moxham's specification it is submitted that the two pieces to be welded here are of practically the same mass as one another, and consequently no difficulty is experienced, unless the difficulty which Moxham provides for by isolating part of one of the members in order to localise the heat supplied by the passage of current therethrough, as if the whole cross section of the rail were to be welded at once the current required would be enormous.

Kyre's specification discloses the form of welding machine, but as the applicant does not claim,

a machine for performing the operation of welding but a process, it is submitted that beyond disclosing a machine for electric welding Eyre has very little bearing upon the applicant's process.

The applicant therefore submits that the process which he has disclosed in claims 1, 3 and 5 are not found in either of the specifications which the Examiner has cited, either individually or collectively as no person skilled in the art, from a perusal of these specifications would be put in possession of the applicant's process without exercise of the inventive faculties.

In view of the above these 3 claims are respectfully resubmitted for the Examiner's consideration.

Cancel claim 4.

With regard to claim 2, which the Examiner has rejected on Cowderey and Moxham, the applicant would refer him to what has been said above with respect to claims 1, 3 and 5.

Re-number claims 5 to 11 as 4 to 10.

With regard to claim 7 which the Examiner has rejected on De Laval of record taken with either Cowderey and Moxham, the applicant would point out that in this claim he has set forth a turbine element having partially isolated portions and blades welded thereto. In neither of the specifications cited by the Examiner against this claim is a turbine blade element disclosed at all having the blades welded to the carrier, as in De Laval's specification the applicant is unable to discover how the blades are formed, and from the appearance in the drawings

he concluded that they are formed integrally with the carrier.

With regard to claims 8 and 9, which are rejected as not being patentable over allowed claim 7, the applicant cannot agree with his view, as the differentiating feature of uniformly spaced blades welding to the carrying element appears to him to be a sufficient differentiation from claim 6.

With regard to claim 10 the applicant can here only repeat what he has said with regard to claim 7, that De Laval discloses no turbine element having the blades welded thereto, and consequently he does not consider that De Laval's patent is in any way a disclosure of the blade element shown in the applicant's specification.

In view of the above remarks it is respectfully requested that the Examiner will reconsider the case and the appliant hopes that it will soon be passed to an early allowance.

Insert new figure 4a filed herewith and the following claims:-

I' per J

11. A process for electrically welding masses of dissimilar cross-section of conductivities consisting in equalising the heat capacities of the masses in the vicinity of the welding spot and passing current through the point of contact of said masses.

12. Process of electrically welding masses of dissimilar cross-section of conductivities consisting in reducing the heat capacity of a mass of greater conductivity, increasing the heat capacity of the mass of lesser conductivity and

passing current through the point of contact of said

wires.

AEW

DEPARTMENT OF THE INTERIOR
UNITED STATES PATENT OFFICE
WASHINGTON

Jan. 14, 1910.

Sebastian Z. de Ferranti,
c/o Spear, Middleton, Donaldson & Spear,
Washington, D.C.

Please find below a communication from the EXAMINER in charge of your *application,* #208,034, filed May 14, 1904, for "Process for Electrically Welding Turbine Blades to their Carrying Elements".

E. B. Moore,
Commissioner of Patents.

Responding to amendment filed Dec. 8, 1909.

The oath referred to in the first paragraph of the above amendment has not been received.

Figures 12 and 13 were not filed with the last amendment, and therefore can not be entered, as directed in lines 7 and 8 of page 1 of the amendment.

The brief description of figure 4^a has not been entered in line 20 of page 2, as the place in said line where the same should be entered has not been designated. The entry of new figure 4^a is refused, as it does not appear to be necessary in order to make clear the invention claimed and is held to involve new matter.

Claims 1 to 4 are rejected as of record. The patent to Cowdery alone is considered to anticipate the claims. The rake parts in Cowdery are electrically welded and held by clamps, and these clamps will cause a material increase of the part having the relatively small mass of metal. Is not the heat conduction limited by making a projecting portion comparatively small relative to the rest of its surrounded portion,? If so, claim 1 should bring this out. This, however, will not aid in conferring patentability to the claim. The steps set forth in claims 3 and 4 are not all shown, namely, the increasing the volume of the blades.

de Ferranti, #208,034--2.

Claim 5 stands allowed, and also claim 6, subject to an amendment in next to the last line which will bring out the fact that each of the blades is welded to a plurality of the rings. As the claim was amended, it does not bring out this feature so as to bring out the utility of the projecting rings.

Claim 7, and also claims 9 and 10 are rejected on the ground that they are directed to the same invention as that for which applicant has already received a patent, namely, de Ferranti, #274,398, De. 24, 1907.

Claim 8 is rejected as not patentably different from that allowed in claim 6 (former 7), especially in view of De Laval, of record, which shows that it is old to have the blades "spaced uniformly"

Claims 11 and 12 are required to be canceled, as they are for a process of electrically welding metals, examinable in another division of the office, in the same class as Lachman, #923,128, May 25, 1909, and Moxham, #497,808, May 23, 1893, (219-10), and they are for an independent invention from that for which claims have been prosecuted before the office (see ex parte Belle, 110 O.G., 1728).

E.A.P.

C.A. Nixon .

Examiner, Division 13.

APPLICATION ROOM

RECEIVED
MAR 10 1910
Division 13, Paper No. 22
Amendment J& Oath.

Room 329
S.Z. de Ferranti
Serial No. 208034.
Filed May 14th, 1904.
Process for electrically welding turbine blades to their carrying elements.

To the Commissioner of Patents.

Sir,

This amendment is in reply to the Official action of January 4th, 1910.

A new Oath is filed herewith.

With regard to figures 12 and 13, the applicant believes that the hand-made drawing of these figures was filed with the amendment replying to the Office action of June 5th, 1908, and applicant would esteem it a favour if the Examiner would kindly ascertain whether the drawing has not been mislaid by the Office.

Cancel brief description with regard to figure 4^a directed to be entered on page 2, line 20.

never been added → Cancel figure 4^a.

The above figure was prepared in accordance with the Examiner's requirements as expressed in the Official letter of May 24th, 1909. As, however, the Examiner considers it now to be superfluous, the applicant has decided to withdraw this figure.

Claim 1, line 4, erase "limiting the heat conduction"

Line 5, erase "between" and insert therefor "partially isolating"

Line 5, erase "and relatively great mass" and insert therefor "from the remainder of the carrier"

Claim 2, line 6, after "rotor" insert "and enclosing the blade between clamps"

Erase claim 4.

With regard to these claims it is respectfully submitted that as now drafted they clearly differentiate the applicant's invention from that of Cowdery of record.

In the first place the applicant would point out that the arts of rake-making and turbine construction are not in any way allied to one another, so that even if the applicant's invention had been partially disclosed in an invention with regard to rakes, it could hardly be fair that a turbine constructor, now that the art has assumed such huge proportions, should be chargeable with the knowledge of an art so distantly related to the one upon which he is engaged.

In the second place, the applicant would point out that the problem which was presented for his solution in connection with the blading of rotors or stators in turbine manufacture, was not in any way analagous to that with which Cowdery was faced in making his rake. In the first place the cross-section of both parts of Cowdery's rake are practically identical, as the bar upon which the teeth are formed is of the same cross-section as the fork carrying the handle. The only interpretation which can be put upon the language used by Cowdery consistent with his disclosure appears to be, that the part carrying the teeth of the rake and the part carrying the fork were primarily raised to the welding temperature by the

electric current before being pressed together and welded. This is apparent and indisputable from the terminology used in lines 56 and 57 of Cowdery's specification.

Now, any construction put upon the present specification involving knowledge of the art developed after the date of Cowdery, would appear to be contrary to all the canons of construction in construing patent specifications. It must also be remembered that Cowdery's specification was filed in the year 1891, so that it cannot be presumed that the problem to be solved in connection with the union of parts by electric welding was too well understood. Further, Cowdery's description is very meagre and no diagram of the circuits proposed, or any full directions with regard to the same has been given in his specification. Had Cowdery shown the method in which he intended to apply the electric current for the purposes of uniting the parts together, then there would be no room for argument, but as his specification must be construed in the light of knowledge available at the date of his application, and as the construction of his specification points to a totally different process from that which the applicant uses, the disclosure in Cowdery ought not to be strained in order to prevent the applicant from obtaining protection for an invention which must be admitted is of paramount commercial importance.

The problem which the applicant had to solve was that of welding a blade to a rotor or other part of a turbine. It is well known that the blades involved are of exceedingly small mass in

comparison with that of the rotor, so that if the end of the blade were pressed against the rotor without any initial proportioning of its surface at the welding point, then the only result would be burning away from the blade. The applicant, however, in the course of his experiments and investigations foresaw that if an efficient weld was to be obtained then it was necessary that both parts involved should rise to the welding temperature. This result he was enabled to obtain, by partially isolating the welding part upon the larger mass, and as this partial isolation prevented the flow of heat from welding point by conduction, he was thus enabled to obtain an exceedingly good weld between the blade and the part carrying the same. In fact, so strong is the weld obtained by applicant's process, that the blades can be hammered over at right angles without the weld giving way.

In view of the fact that the present methods of fastening blades are exceedingly crude, and reliance is placed upon caulking and other old-fashioned methods of obtaining rigidity, it will be evident that the idea of forming the blades separately from the rotor while uniting them thereto in such a manner that they may be said to be practically integral therewith, is an invention of the highest importance. To an unprejudiced mind, such an advance in the art of turbine construction is one possessing great merit, and obviously the person introducing or inventing the same ought to have protection for his invention. Further, the applicant obtains this satisfactory weld not by clamping both pieces as is

done by Cowdery, but by differential treatment of the parts concerned in order to obtain the efficient result. As the conductivity of the larger mass such as the rotor, is so great that the heat is conducted rapidly away from the welding point, it was necessary that some means should be devised for retarding this flow of heat and localising it, so that the necessary temperature may be obtained. This, as has been stated above, was effected by the applicant by the partial isolation of the welded parts of the rotor, but when it comes to the treatment of the blade, the applicant increases its mass artificially by enclosing the blade with the exception of its tip in the clamping edges. By this means, it will be evident that the conductivities as regards heat of the two parts can be practically balanced, so that both portions will rise to the welding temperature at the same time. On the application of pressure interpenetration of the parts is effected, and an exceedingly good weld obtained of the blade to its carrying element.

The turbine constructor in search of a method of fastening the blades onto the rotor or stator as the case may be, could hardly be presumed to find in Cowdery the information with directions necessary to enable him to carry out the applicant's process, and invview of this fact as well as the fact of the extreme utility of the applicant's invention, it is hoped that the Examiner will now withdraw his rejection to these claims.

1258

Re-number claims 5 and 6 as 4 and 5.

Claim 4, line 4, erase "of at least"

Sub K' line 5, erase "two" and insert therefor "to a plurality"

#208,034. filed May 14, 1904. for "Process for Electrically Welding Turbine Blades to Their Carrying Elements".

E.B. Moore,

Commissioner of Patents.

6-311

Responding to amendments filed Mar. 14 and Apr. 14, 1910.

Applicant's argument has been fully considered, and action on the claims taken as follows:

Claim 1, 2 and 3 are each rejected on Coudery, taken with Eyre, of record.

Claim 4 (formerly considered allowable) is now believed to be met in the above references, and it is rejected on Coudery taken with Eyre.

Claim 5 is allowable.

In view of the fact that the examiner is satisfied that no patentable process is disclosed in this application, this action may be taken as final for purposes of appeal, if applicant so desire.

Amendment L

Room 329
S. Z. de Ferranti.
"Turbine Blade Welding".
Filed May 14th, 1904.
Serial No. 208,034.

To the Commissioner of Patents.

Sir.

Reply to Office Letter dated April 26th, 1910.

It is very much regretted by Applicant and his Attorneys that the Examiner after having allowed claim 4 some twelve times or so during the last six years should now change his opinion and reject it. Neither are the reasons for such rejection understood, since Eyre of record does not appear to bear on the point covered in any way at all. The whole of Applicant's difficulties arose from the large mass of the carrier contrasted with the small mass of the blade. Circumferential grooving of the carrier was proved to be one good way of overcoming this difficulty. It is very respectfully pointed out that the problem above set forth never presented itself to Eyre since the bars he welds together are of equal cross section; neither is grooving of any kind employed by him.

Applicant, moreover, ventures to doubt whether even in the year 1910, the art of examining claims has reached a degree of precision sufficiently high to enable any distinction to be drawn between the patentability of the process and article respectively claimed in claims 4 and 5.

In this view he believes he is supported by

the opinion of the Examiner himself as expressed in the Office letter of December 16th, 1905.

The following statement appears therein:-

"Whether the invention is in the process or the article may be somewhat doubtful and for that reason it is believed to be proper to allow both claims in the same application."

For the above reasons, claim 4 is very respectfully resubmitted for reconsideration.

Claims 1 and 3 are also respectfully resubmitted on the ground that in order to meet the peculiar difficulties of the turbine blade welding problem, carrier and blade have to be treated differentially, the former having to have its mass produced and the latter having to have its mass virtually increased as by the copper blade clamps. No such differential treatment is to be found in any of the references.

Claim 2 is likewise resubmitted on the ground that the method of producing a bladed turbine rotor therein set forth is simple and less expensive than any hitherto practised inasmuch as the symmetry of the rotor being maintained throughout, the final step of balancing with lead can be successfully admitted. This advantageous omission arises solely from Applicant's novel process.

The feature of "symmetry" set forth in the preceding paragraph is indeed believed by applicant to be of such great practical importance that he requests that the following two claims dealing specifically with this point may be made of record:

It may be remarked parenthetically that it is

believed that claims on these lines were favourably entertained by the Examiner in an oral interview in the Spring of 1907 or thereabouts, but through some mischance, such claims do not appear to have been definitely submitted for action on the merits.

5 &. The method herein described of constructing a turbine wheel, ring or drum, the same consisting first in forming said wheel symmetrically in relation to its centre of rotation with the parts next to the welding points reduced to properly conform to the volume of the blades and electrically welding said blades at the said points whereby the symmetry of the wheel is maintained.

7. A turbine wheel, drum or ring having a periphery made to conform to the volume of the blades at the points of attachment of said blades and symmetrical in relation to the centre of rotation and a series of blades of uniform dimensions welded symmetrically to a plurality of said points, substantially as described.

Very Respectfully,

S.Z. de Ferranti,

Ser. No. 308,034, filed May 14, 1904, for "Process for Electrically Welding Turbine Blades to their Carrying Elements".

E.B. Moore,

Commissioner of Patents.

Responding to amendment filed June 25. 1910.

In specific reply to applicant's comment on the Eyre patent, it will be stated that this patent was cited to show the use of clamps which can not help but perform the same function as applicant's clamps which hold the turbine blades. In further consideration of this patent, in the middle of page 2 of the above amendment, applicant states that "no such differential treatment is to be found in any of the references". If in the Eyre device one of the pieces to be welded were so large that no clamp would be necessary, the other clamp would perform the function denied by applicant.

New claim 6 is rejected as drawn to an aggregation of the manner of forming the turbine wheel proper, and the specific method of attaching the blades. The examiner sees no reason for changing his action on the first four claims, and these are each rejected on Coudery taken with Eyre, of record.

Claim 5 and 7 are allowable.

S. Z. de Ferranti.
Process for electrically welding turbine blades to their carrying elements.
Serial No. 208034.
Filed May 14th. 1904.

To the Commissioner of Patents.

Sir,

This amendment is in reply to the Official letter of the 23rd July, 1910.

With regard to the specification of Eyre which the Examiner has relied upon in conjunction with Cowdery for the rejection of the applicant's claims, it is pointed out that the Examiner has evidently misunderstood the point of the applicant's last argument. The applicant has stated "that no such differential treatment is to be found in any of the references." in page 2 of the amendment filed June 25th, 1910, but the Examiner appears to think that if one of the pieces to be welded in the Eyre device was so large that no clamp would be necessary the other clamp would perform the function ~~served~~ desired by the applicant. To this the applicant would reply that supposing one of the parts being welded by the Eyre machine were so large as to render clamping unnecessary, then the problem would be such that some process similar to the applicant's would require to be proposed in order to effect the welding of one piece to the other. In Eyre's specification no suggestion is made of the manner in which articles differing largely in volume can be successfully welded together, and throughout the whole of the specification his attention is directed to the

welding together of practically identical pieces. The difficulty therefore, which Eyre encountered cannot be the same as the applicant's in which the whole problem was the manner in which a part of small volume like a turbine blade could be welded to a part of large volume, such as a rotor or stator. If welding were attempted as the Examiner suggests, by ~~applying~~ employing Eyre's machine, with one part in one clamp and the other part of such large dimensions as not to require a clamp, then ~~if it were attempted to weld them together~~ it would be found that the large volume of the larger piece would prevent any weld being formed owing to the difficulty in raising the parts to the welding temperature. This in short, was the difficulty with which the applicant was faced, and he overcame this difficulty by reducing the cross-section of the mass of larger volume to substantially the same volume as the part to which it is to be welded.

There is no suggestion in the whole specification of Eyre of reducing the cross-section of one of the parts to be welded at all.

With regard to Cowdery's specification, the applicant would point out that here there is disclosed a process of electric welding, but this process although bearing a ~~type of~~ resemblance to surface ~~resembling~~ the applicant's, in reality is not by any means so closely related as would seem at first sight. In the first place, the art to which Cowdery's specification relates, is that of making rakes, and the problem with which he was faced cannot be termed analogous to that with which the applicant was faced. Further, there is no suggestion in

Cowdery's specification that the heating effect of the current was due to the resistance at the contacting points of the two ~~pieces~~ parts, while from a perusal of the specification it would appear that each of the pieces were individually clamped between electrodes, so that the ohmic resistance of the parts between the electrodes was responsible for the raising of the temperature. In support of this view, attention is directed to line 51, in which it is stated: "In electric welding, the two pieces to be welded are suitably clamped in the terminals of a circuit carrying a current of large volume," and then in line 56, where it is stated that "the meeting surfaces of the pieces which have been heated to the welding heat by the current," are brought against each other." The inference then is that before actual contact of the parts takes place, they have been raised to the welding temperature. Now the only possible way in which this could be done by electric welding is certainly not by leading the current across the point of contact of the two pieces to be welded, as in that case they would have been brought together before their temperature started to rise.

Cowdery's specification, then, in view of these two extracts which the Applicant has selected, points to a method of electric welding entirely different from that which Applicant uses, & claims so that it would appear that the applicant's process is novel in view of both Eyre and Cowdery's specifications.

Further, when Cowdery's article is considered it will be evident that he was not faced with the same difficulty as the applicant, because the rake of Cowdery is naturally formed with a cross-section

similar to the fork to which it is attached, and that there was no partial isolation of the parts necessary in order to reduce the volumes of the metal at the welding point.

Again, in each of the specifications of Eyre and Cowdery, the use of two clamps one for each part to be welded, is insisted upon. The applicant, however, only uses one clamp for the blade and does not use one at all for the turbine carrying element, in fact, the difficulty of applying the process or the machine shown in either Cowdery or Eyre's specification, would consist in the fact that only one of the parts could possibly be held in a clmap, so that the fact of the applicant using only one clamp while prevented from the nature of his process from using the other, differentiates it to a great extent from either that disclosed in Eyre or Cowdery's specifications.

When it is considered that the art of turbine making has advanced with such rapid strides, the necessity of the discovering some way of uniting the blades to the rotor in an effective manner, would be accounted of exceeding importance. It is well known that the present method of fastening the blades of turbines totheir carrying elements is open to great improvement, as it is necessary to use caulking strips or some other antequated means for holding the blades in position. The ideal method of fastening blades is obviously to arrange matters so that they will practically form an integral part of the rotor or stator. This advantage the applicant believes he has been the first to accomplish as by electrically welding the blades to the carrier in the way in which he has disclosed in his

specification, a joint of great strength and efficiency is obtained. There is further not the slightest chance of the blades working loose during working of the turbine, as by means of his electric welding process, the applicant is enabled to fasten the blades to the rotor in such a manner that the blades may be bent over at right angles without in any way breaking or affecting the weld. When this fact is considered, it will be evident that the advantages of the applicant's process are very great.

To sum up the applicant's contention, Cowdery's specification he maintains does not show a process in which it is distinctly stated that the current is led across the point of contact of the two parts to be welded. Further, the arts of rake and turbine making are so far removed from one another that the transformation of a process suitable for making rakes into a process suitable for welding the turbine blades to their carrying elements might well evolve invention. Again, Eyre's specification discloses an electric process in which the current is led across the points of contact of the two parts to be welded, but in this case there is no solution of the problem disclosed of welding a part of small mass to a part of a relatively greater mass by partially isolating the parts of the greater mass at the welding spot to approximately the cross-section of the part to be attached thereto. Consequently, even in full possession of the knowledge disclosed in both Eyre's and Cowdery's specification, the applicant maintains that a person skilled in the art could not obtain possession of the applicant's process without some

~~employment of the inventive faculties.~~

Insert the following new claims:-

8. A process fo uniting two parts together consisting in utilising portions only of the individual juxtoposed surfaces for the transference of electric heating current so as to limit the heating effect of said current substantially to said portions and applying pressure so as to unite the parts by a weld of less area than that of the juxtaposed surfaces.

9. A process for uniting two parts together consisting in utilising portions only of the individual juxtaposed surfaces for the transference of an electric current the utilised portions being prepared so as to localise the heating effect of said current and applying pressure to unite the parts by a plurality of isolated electric welds.

10. A process for uniting two parts together consisting in leading an electric current across portions only of the individual juxtaposed surfaces of the parts and applying pressure to said parts so as to intergrally unite the individual juxtaposed surfaces together by a plurality of isolated electric welds.

11. A process for uniting two parts together consisting in forming projections on the individual juxtaposed surfaces of said parts leading an electric current across the parts by way of said projections and applying pressure to unite the individual juxtaposed surfaces by a plurality of isolated electric welds.

12. A metal article having component

employment of the inventive faculties.

In view also of the fact that the applicant is enabled to provide a process which has been desired for a long time, viz., to unite turbine blades to their carriers in a manner which is effective expeditious and inexpensive in practice, shows that the process disclosed by the applicant is of great utility.

In view of the above the applicant maintains that the claims rejected by the Examiner contain patentable subject matter and respectfully solicits a reconsideration of the rejected claims.

Please add the attached claims and attention is called to the remarks appended hereto.

Respectfully,

S.Z. de Ferranti,

By

Spear, Middleton, Donaldson, & Spear
per Walter Donaldson,

ATTORNEYS.

WB/LW.

parts thereof united by a weld of less area than that of the juxtaposed surfaces.

13. Composite metal articles having individual abutting portions united together by a plurality of isolated welds.

14. A metal article having a plurality of current localising portions formed on one of its surfaces.

The above new claims are submitted to the Examiner's consideration as being patentable over the state of the art disclosed by the results of the Official search. The above claims are clearly differentiated from the process disclosed in Cowdery's patent of record. In Cowdery's specification, in an article produced in accordance with the directions given therein, the weld between the parts is spread over the whole of the individual abutting portions, the parts a', being the individual portions of the head A which abut against similar parts of the braces B. In this process, therefore, the whole of the opposing surfaces are operative in conducting the heating current and the whole of the abutting portions are available for welding purposes. This means when the cross-section becomes large, that a much greater amount of current is utilised in uniting the parts than is absolutely necessary, as by utilising the applicant's process if the current is restricted to definite portions of the abutting surfaces then the parts will be united together by a plurality of isolated welds, which for all practical purposes is strong enough to withstand ordinary conditions of working.

In proof of this, the applicant finds that when welding turbine blades to their carrying elements by the method which he has disclosed in this specification the blades may be hammered over at right angles without any signs of the weld giving way. The applicant, therefore, utiliges only a portion of the area which might be utilised for welding, and thus by limiting the amount of cross-sectional area available for the conduction of the current, the heating effect of the same is localized and the amount of corrent required for the weld reduced to the absolute minimum. This process has not been disclosed in any of the specifications cited by the Examiner, and consequently the applicant respectfully submits that the new claims embody patentable subject matter. The process so far as the applicant knows, is novel. The parts are united together in an exceedingly efficient manner. Further, the amount of current is reduced to the bare minimum requisite for enabling the desired strength of weld to be obtained, and in view of this fact the amount of current used and the expense of each weld is reduced to the absolute minimum.

In view of these advantages the applicant very respectfully requests a reconsideration of the case, and hopes that it will soon pass to an early allowance.

Respectfully,

S.Z.de Ferranti,

By Spear, Middleton, Donaldson & Spear.
per Walter Donaldson.

E.B. Moore.

Commissioner of Patents.

6-321

In response to amendment filed Dec. 5, 1910.

Concerning the argument made by applicant especially the sentence beginning in line 15, page 2, of the above paper, the subject matter of this sentence is shown to be old in Coudery, of record.

Claims 1 to 4 and claim 6 are each rejected in accordance with the Office letter of July 23, 1910.

New claims 8, 9 and 10 are each drawn to a method of electric welding and constitute a shifting of ground. They are therefore required to be canceled under ex parte Selle, 110 O.G 1728.

Claims 8 and 9 are additionally rejected as incomplete since they omit the step of heating.

Claims 8 to 14 are each rejected on Coudery and also on Moxham, of record.

Claims 12, 13 and 14 are each also rejected on DeFerranti, of record.

Claims 5 and 7 are believed to be allowable.

It is obvious that a clear issue has been raised between applicant and the examiner and the case should be prosecuted to an early final issue.

Amendment. N

APPLICATION ROOM
DEC 18 1911
U. S. PATENT OFFICE

To the Commissioner of Patents.

Sir,

This amendment is in reply to the Official letter of January 6th, 1911.

With regard to the first paragraph of the Official letter in which the Examiner takes objection to certain parts of the argument filed on the 5th December, 1910, the applicant would point out that the paragraph referred to simply states the problem with which the applicant was confronted. Further, he was pointing out the difference between his process and that described by Eyre of record, and the difference between the applicant's process and that of Eyre is stated to be that in Eyre the problem was for uniting two pieces of the same cross-section, while the applicant had to unite two pieces of greatly differing masses. The Examiner states that this is old as shown in Cowdery's specification; the applicant, however, does not agree that his process is disclosed in Cowdery's specification, and the difference of the masses dealt with by the applicant are very much greater than the difference in the masses dealt with by Cowdery.

Applicant admits that Cowdery states in his specification that the object of the particular method which he employs is for the purpose of forming welds between the heads and the braces, without

heating the entire head. If it is assumed that the difficulties of Cowdery and the applicant are the same, yet it does not necessarily follow that the particular methods in which the difficulty was over come are indentical. Further, if it is assumed that the difficulties encountered in both are indentical, then there may also be subject matter in two different solutions for overcoming the same difficulty, so long as the methods of solution are not the same.

The question therefore comes to be whether the process disclosed in Cowdery's application is identical with that which the applicant has disclosed. The applicant must emphatically state that Cowdery's method is essentially different from his.

On a fair construction of Cowdery's specification, no other interpretation can be put upon the document than that the parts to be united are first brought separately to the welding point before pressure is applied, so that in forming a rake according to Cowdery's specification, two distinct operations are necessary, first by means of an electric current to place the ends to be united between clamps, raising each of the parts individually to the welding temperature, and then forcing them together to form the weld. In the applicant's process, however, the method of procedure is entirely changed, and both the operation of heating and forcing together under pressure are performed simultaneously. Further, in the applicant's process, no clamps are necessary and the current being led across the points of contact of the two parts to be united, allows the parts to be forced together whenever they have

softened under the influence of heat to the required extent. It is therefore submitted that this essential difference exists between Cowdery's process and the applicant's viz., that in Cowdery's process the parts to be united are separately raised to the welding temperature before being forced together under pressure, while in the applicant's process the operations of heating and forcing together take place simultaneously. It is thought that this difference is sufficient evidence of the inventive faculties having been exercised, and raises the method of Ferranti apart from commercial considerations whatever, to the dignity of invention.

Erase claims 8 to 14.

Respectfully,

Sebastian Ziani de Ferranti,

By- Spear Middleton Donaldson & Spear

208, 034, filed May 14, 1904----

Process for Electrically Welding etc.

E. B. Moore.
Commissioner of Patents.

Replying to amendment filed Dec. 18, 1912.

This case has been transferred to Division 3 and a farther search has disclosed the patent to Thomson, 487, 302, Dec. 6, 1892, 219 - 10, Fig. 4 of which is considered to anticipate claims 1 and 2.

Claims 3 and 4 are considered allowable.

Claims 5 and 7 are for an article independent of the process of manufacture and of a recongnized different art. Division is therefore required between claims 5 and 7 and the remaining claims. It is not clear, however, why these claims are not barred to applicant in this application on account of his patent # 874, 398, Dec. 24, 1907, Steam Engines, Rotary. There seems to be no line of division between the claims in that case and claims 5 and 7.

Claims 6, as stated in the last Office letter is still considered to be merely an aggregation of independment steps since the details of broadly forming a balanced body or carrier has no relation to the specific welding steps. This claim is rejected upon the ground of being an aggregation of independent steps. The steps of balancing the body and symmetrically arranging the welding points is considered to be

merely mechanical skill.

It is noted that the amendment to page 3 (Apl. 30, 1909) is not inserted at the right place, "and" should have been inserted at the end of line 9 and the description of Fig. 12 and 13 should stand between line 9 and 10. Applicant's attention is also called to the fact that no figures 12 and 13 agreeing with the description at this place and that inserted on page 5, xx between lines 17 and 18 have ever been inserted in the drawings. This is considered necessary in order to support the limitations to claims 1 and 2 and the statement inserted at the end of the specification by amendment of Apl. 19, 1907,

The objection as to the drawings being photolithographs, still applies.

Wm J Rich,

Examiner, Div. 3.

Amendment C

U. S. PATENT OFFICE,
DEC 31 1912
DIV. 3.

Room 175.
S. Z. de Ferranti.
Serial No. 208034.
Filed May 14th, 1904.
"PROCESS FOR ELECTRICALLY WELDING &c."

To the Commissioner of Patents.

Sir,

This amendment is in reply to the Official letter of January 20th, 1912.

With reference to the U. S. Patent to Thomson, No. 487302, which the Examiner considers anticipates claims 1 and 2, the applicant, after careful consideration of the specification and drawings of the above patent, cannot agree with this view of the Examiner.

In Thomson's specification a method of electric welding is described and illustrated by means of drawings and the whole of the description and the drawings relate to a process of attaching parts of different mass together by electric welding. On page 1, line 45, the following statement occurs: "The present invention consists in uniting pieces in such a manner that a greater current passes through one piece than through another or others concerned in the operation, whereby if the one piece be larger than the other it may reach the welding temperature at the same time as the others."

In the whole of the methods illustrated, Thomson effects the welding together of two pieces of different mass, by passing a greater current through the part of larger mass than that which passes through the smaller mass.

In Figure 4 to which the Examiner especially draws the Applicant's attention, the larger mass, B, is shown

which is provided with two small projections, J and J', to which the small pieces, a and b, are welded respectively. In this method it is stated on Page 2, line 103, that the arrangement for the supply of the current to the pieces between the clamps, are to be made on the same principles as set forth in connection with Figures 1 and 2, the object being to traverse the larger piece by a larger amount of current than the smaller piece, whereby the heating operation in each goes on proportionately.

In the only example which Thomson shows of uniting a larger mass to a single smaller mass, he effects this as described with reference to Page 2, at lines 30-39, by utilising a third piece for the purpose of increasing the current passing through the larger piece, so as to raise the pieces to be welded to the desired temperature, and it is evident that as this principle is also to be applied when welding, in Figure 4 for example, the part, a to the part B, it would be necessary to apply a current through the part, b, initially and temporarily for the purpose of raising the parts, B and a, to the desired welding temperature. Also in claim 1, he has stated as the subject matter of his invention, the herein described improvement in welding metals electrically consisting in making contact with both the pieces to be united and passing a current of greater strength through one piece than the other.

Taking Thomson's specification as a whole, it is evident that the only method which he has disclosed of welding parts of different mass together, is to pass a greater current through the larger mass than through the smaller one. In no case has he disclosed a method like the applicant's, in which the same current passes through

both masses being welded.

In all cases where Thomson desires to weld two parts together, of different mass, he applies current through a third part to the larger mass in the initial stages of the operation, in order to heat the parts proportionately. In no case is there the slightest suggestion in Thomson's process of welding two parts of different mass together, without the aid of a supplementary piece to pass a greater current through the larger piece than the smaller piece.

In order to clearly differentiate the applicant's claim from Thomson of record, the applicant makes the following amendments to claims 1 and 2:

Claim 1, line 9, before "electric" insert "and uniform"

Claim 2, line 8, before "electric" insert uniform"

It is submitted that these amendments clearly differentiate the applicant's process from that described in Thomson's specification.

Cancel claims 5 and 7, and re-number claim 6 as claim 5.

The applicant cannot agree with reference to claim 6, that this claim is merely an aggregation of independent steps. In the construction of rotors, it is well-known, that one of the most important parts is the balancing of the rotor, as if the centre of mass does not coincide with the centre of rotation, then vibrations of greater magnitude will be set up owing to the speed at which the rotor revolves.

In the present construction of rotors, after all the blades have been attached, it is necessary to balance the rotor by drilling holes in the required positions, so as to remove excess of metal at these parts, so that according to the ordinary construction, the

procedure is to form the rotor first and thereafter to make its mass symmetrical by removing metal at the necessary positions. This method of balancing is at best only approximate, while it also requires the exercise of much skill and ingenuity to determine the precise spot from which the metal ought to be removed to give the best results. According to the applicant's process, however, the rotor is formed symmetrical at the commencement, and as the blades are all equal to one another, and symmetrically disposed with regard to the axis of ~~the casting~~ rotation, it will be evident that ~~the~~ a considerable expenditure of skill and time is prevented by the applicant's invention.

The applicant considers that the welding of blades on to the body has a certain relationship with the balancing the same, in view of the fact to which the rotor is applied, as the removal of the metal for the purpose of welding is effected in such a manner as to leave the rotor absolutely symmetrical, after the parts have been removed by the welding operation.

In view of the above, a reconsideration of this claim is respectfully requested.

With regard to the amendment of April 30th, 1909, page 3, insert "and" at the end of line 9, and the description of Figures 12 and 13 between lines 9 and 10. A drawing containing new Figures 12 and 13 is filed herewith.

The objections to the drawings are being complied with, bur it is reapectfully requested that those at present on file be allowed for examination purposes.

A new set of hand-made drawings will be filed before issue of the case.

An early allowance on the case is respectfully requested.

Respectfully,

S. Z. de Ferranti.

208, 034, filed May 14, 1914,

Process for Electrically Welding etc.

E. B. Moore,

Commissioner of Patents.

Replying to amendment filed Dec. 30, 1912.

The amendments to claim 1 and 2 do not apply, the term "electric" not being found in lines 9 and 8, respectively, these claims.

Since claims 5 and 7, for the article, have been canceled the title in the preamble should be amended.

Applicant's remarks fail to point out any alleged relationship between the steps of balancing the rotor and welding blades thereto. It seems to be obvious that the rotor can be balanced, either before or after attaching the blades, Claim 5 is again rejected for this reason.

Applicant states that substitute drawings will be filed but the Office practice has been changed so that it is desirable to correct the present drwings rather than to file new ones. No action can be made upon claims 2 and 3 in view of the fact that the amendments do not apply.

U. S. PATENT OFFICE
DEC 31 1913
DIV, 3

To the Commissioner of Patents:-

Responsive to office action of January 18, 1913 in this case, please amend as follows:-

In amendments to claims 1 and 2, the line should have been 7 instead of 9 and 8 respectively. In order to avoid confusion the claims 1 and 2 are herein given as it is desired they should now read.

1. The method of attaching turbine blades to their carrier of relatively great mass which consists in adjusting the heat capacity of the localized area of the carrier at the point of attachment by partially isolating these areas from the remainder of the carrier so that a welding temperature may be reached notwithstanding the cooling effect of the mass of the carrier, and passing a uniform electric heating current directly through the carrier and by way of the clamps through the blades to weld the blades in succession to the carrier, substantially as described.

2. The method of attaching turbine blades to their rotor carrying elements one by one, consisting in equalizing the heat capacity of the welding parts by limiting the conducting areas of the carrier at the points of blade attachment symmetrically in relation to the axis of rotation of the motor, and enclosing the blades between clamps so that on heating locally by a uniform electric current, the blades

and carrier rise to approximately the same temperature on welding the blades to the carrier so prepared, substantially as described.

Change the title to --Process for Electrically Welding Turbine Blades--.

The Office will be asked to correct the drawings.

Applicant trusts that after this amendment has been made claims 1 and 2 in view of the argument last filed will be found to be acceptable and will be allowed.

With regard to the remark by the Examiner that no relationship exists between the step of balancing the rotor and welding the blades thereto, it is submitted that it appears to us that such a relationship exists, as by the method which the applicant discloses of attaching the turbine blades to their carrying elements, the symmetry of the rotor is preserved.

It is quite true, as the Examiner remarks, that the rotor may be balanced either before or after attaching the blades, but in the present case both these operations are dispensed with, as owing to the fact of the blades being spaced symmetrically round the circumference of the motor, the symmetrical disposition of the masses is preserved, and the balancing operation previously required in the manufacture of rotors, dispensed with.

Respectfully,

S. Z. de Ferranti,

THE COMMISSIONER OF PATENTS,
WASHINGTON, D. C.

2—181 A. T. D. **Serial No.** 208034

DEPARTMENT OF THE INTERIOR

UNITED STATES PATENT OFFICE

WASHINGTON Dec. 31, 1914.

Sebastian Ziani de Ferianti,

Sir: Your APPLICATION for a patent for an IMPROVEMENT in Process for Electrically Welding Turbine Blades,

filed May 14, 1904, has been examined and ALLOWED.

The final fee, TWENTY DOLLARS, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent on this application will be withheld, unless renewed with an additional fee of $15, under the provisions of Section 4897, Revised Statutes.

The office delivers patents upon the day of their date, and on which their term begins to run. The printing, photolithographing, and engrossing of the several patent parts, preparatory to final signing and sealing, will require about four weeks, and such work will not be undertaken until after payment of the necessary fee.

When you send the final fee you will also send, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If you desire to have the patent issue to ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of final fee.

After issue of the patent uncertified copies of the drawings and specifications may be purchased at the price of FIVE CENTS EACH. The money should accompany the order. Postage stamps will not be received.

Final fees will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

Respectfully,

Thomas Ewing
Commissioner of Patents.

Spear, Middleton, Donaldson & Spear,

Washington, D. C.

IN REMITTING THE FINAL FEE GIVE THE SERIAL NUMBER AT THE HEAD OF THIS NOTICE.

UNCERTIFIED CHECKS WILL NOT BE ACCEPTED.

UNITED STATES PATENT OFFICE.

SEBASTIAN ZIANI DE FERRANTI, OF HAMPSTEAD, LONDON, ENGLAND.

PROCESS FOR ELECTRICALLY WELDING TURBINE-BLADES.

1,148,221. Specification of Letters Patent. Patented July 27, 1915.

Application filed May 14, 1904. Serial No. 208,034.

To all whom it may concern:

Be it known that I, SEBASTIAN ZIANI DE FERRANTI, a subject of the King of Great Britain and Ireland, and residing at 31 Lyndhurst road, Hampstead, London, N. W., England, have invented a certain new and useful Process for Electrically Welding Turbine-Blades, of which the following is a specification.

The invention relates to the electrical welding of turbine blades on to the wheels, rings or drums carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an inexpensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier, rapidly conducts heat away from the welding point thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of the blade carrying element in the neighborhood of the welding point so that approximately equal heating occurs in both faces to be welded.

Referring to the accompanying drawings which, with the exception of Figure 4, show the invention applied, by way of example, to a type of parallel flow turbine in which the blades are mounted on the edge of a wheel like body, Fig. 1 is a part side elevation of such a wheel having cross grooves, Fig. 1ª being an edge view; Fig. 2 shows a similar edge view of a modification in which sets of intersecting grooves are adopted; Fig. 3 shows an edge view of a form having circumferential grooves, Fig. 3ª being a section on the line A A of Fig. 3; Fig. 4 shows, in longitudinal sectional elevation, part of a drum carrier to which the blades are welded in accordance with one form of the invention; Figs. 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disk, while Fig. 7 is a part side elevation in which holes are bored through from face to face of the disk; Fig. 8 shows a sectional plan of a form of wheel built up of two dished disks, held apart at their circumferential portions by distance pieces, Fig. 8ª being a partial edge view to a larger scale; Fig. 9 is a similar sectional plan of a modified form of wheel built up of three disks, while Fig. 9ª is a corresponding partial edge view also to a larger scale; Fig. 10 shows a part sectional elevation of a wheel built up of two comparatively thick disks having notched edges, Fig. 10ª being a partial edge view, while Fig. 11 shows an edge view of a form of wheel built up of a series of "stepped" laminæ and Figs. 12 and 13 show a form of clamp and a diagram of the electrical connections.

(It will be seen that all the edge views in the preceding figures are shown as developments for clearness of drawing and not as true projections.)

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

In carrying out the invention according to the form shown in Figs. 1 and 1ª, the turbine wheel or disk is shown at *a*, cross grooves, *b*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded. The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disk, as is shown in Fig. 2 or by cutting circumferential grooves, such as *f*, completely around the edge (see Figs. 3 and 3ª.)

Fig. 4 shows the invention according to one form applied to the case of a drum blade carrier, *a'*; the drum is grooved circumferentially with grooves, *f'*, the intervening collars of metal being then cross-cut to form projecting teeth, *c'*, on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disk, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in Fig. 5, or arranged without particular reference to the position of the blades, (see Fig. 6).

In Fig. 7, a method is shown of removing

metal in the neighborhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disk at a radius slightly less than that of its outside edge. The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficient areas untouched to insure the mechanical strength in the welded joint.

Referring now to Figs. 8 and 8ª, a form of wheel is shown somewhat diagrammatically which is built up of two dished disks, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as *l*, disposed at a radius somewhat less than the maximum radius of the disks, the blades, *d*, being welded in position on their outside edges.

Figs. 9 and 9ª show a type of wheel generally similar to that last described but having an intermediate plane disk, *m*, in addition to the two dished disks, *k*; a portion, *n*, of the hub, *o*, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the disks in their correct relative position may be adopted.

In every case it will be seen that those portions of the carrier to which the blades are to be welded are partially isolated from the body of the carrier by slots, holes and so forth so as to limit the cross-sectional area available for the conduction of heat, and so compel the carrier to rise to the welding temperature. On the other hand to prevent the blades being burnt away, their mass is artificially increased by holding them between clamps or jaws of high heat conductive material such as copper. Thus referring to Figs. 12 and 13, the jaw holder 63, is separated into two branches by means of the slot, 64, each branch carrying a copper jaw, 65, shaped so as to clear adjacent blades. Between the jaws, 65, the blade to be welded is clamped, so as to leave the tip only exposed as seen in Fig. 13, and in order to insure a good contact and rigid holding of the blade in the jaws, a clamping device is preferably arranged in addition to that provided by the spring of the two branches of the jaw holder.

According to the form shown links, 66, are pivoted at 67, to one branch of the jaw holder, while short cross links, 68, connect the links, 66, to the other branch to which they are pivoted at 69. The long links, 66, are curved as shown, and are connected at their non-pivoted ends by the cross-piece, 70, to which pressure to clamp the blade is applied in the direction of the arrow (see Fig. 13) by means of the cam, 71, and the hand lever, 72, both of which are secured to a common axle rotatably mounted on any convenient support, 73. A spring such as 74, serves to return the links when the blade is released.

The necessary electrical connections to affect the welding are shown diagrammatically in Fig. 13, in which G represents an appropriate source of alternating current, and T, a transformer. It will be seen that while the lead, *t'*, may be connected directly to the carrier *a*, as in the example shown, it is necessary on the other hand that current to the blade, *d*, should be conveyed indirectly by way of the jaw holder, 63, and lead, *t²*.

In Figs. 8 and 9, the dished disks, *k*, are indicated as secured to the hubs, *o*, by pressing the inner edges of these disks into grooves and subsequently burring over the hubs to hold the disks in place.

In the modification shown in Figs. 10 and 10ª, two dished disks, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to Figs. 1 and 1ª. Again, that portion of the disk carrying the blades may be built up of a set of thin laminæ, *r* (see Fig. 11) the edges of which are notched as at *s*, the laminæ being assembled in such a way that the notches, *s*, are "stepped" with regard to each other, so that the intervening projections of metal may follow the shape of the turbine blades to be welded to them.

Instead of notching the laminæ, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In an invention such as the present, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

The electric heating current is passed directly through the carrier and by way of clamps through the blades.

By means of my invention it will be seen that the blades are attached to their carrying elements in an expeditious and efficient manner while in the case of rotors a still further advantage is obtained over the methods of blading commonly employed inasmuch as if properly carried out the attachment of the blades by electric welding introduces no change of symmetry with respect to the axis of rotation and consequently dispenses with the tedious operation of balancing otherwise rendered necessary.

Having now described my invention what I claim as new and desire to secure by Letters Patent is:—

1. The method of attaching turbine blades to their carrier of relatively great mass which consists in adjusting the heat capacity of the localized area of the carrier at the point of attachment by partially isolating these areas from the remainder of the carrier so that a welding temperature may be reached notwithstanding the cooling effect of the mass of the carrier, and passing a uniform electric heating current directly through the carrier and by way of the clamps through the blades to weld the blades in succession to the carrier, substantially as described.

2. The method of attaching turbine blades to their rotor carrying elements one by one, consisting in equalizing the heat capacity of the welding parts by limiting the conducting areas of the carrier at the points of blade attachment symmetrically in relation to the axis of rotation of the rotor, and inclosing the blades between clamps so that on heating locally by a uniform electric current, the blades and carrier rise to approximately the same temperature on welding the blades to the carrier so prepared, substantially as described.

3. Process for the attachment of turbine blades to their carriers consisting in partially isolating those portions of the carrier in the neighborhood of the points of attachment of the blades, to limit the cross-sectional area available for the conduction of heat therefrom; artifically increasing the volume of the blades by contacting them with metal masses of high heat conductive capacity and finally welding together the carriers and blades so prepared.

4. Process for the attachment of turbine blades to their carriers, consisting in forming circumferential grooves with intervening rings of metal around the carrier thereby limiting the cross sectional area available for the conduction of heat from the point of attachment so that on heating locally, said blade and said carrier rise to approximately the same temperature and welding each blade to a plurality of said rings, as set forth.

5. The method herein described of constructing a turbine wheel, ring or drum, the same consisting first in forming said wheel symmetrically in relation to its center of rotation with the parts next to the welding points reduced to properly conform to the volume of the blades and electrically welding said blades at the said points whereby the symmetry of the wheel is maintained.

In witness whereof I have hereunto set my hand in presence of two witnesses.

SEBASTIAN ZIANI DE FERRANTI.

APPLICATION FOR UNITED STATES PATENT

JAN 2 1912

Petition with Power of Attorney.

To the Commissioner of Patents:

Your petitioner SEBASTIAN ZIANI de FERRANTI,

subject of the King of Great Britain and Ireland, and resident of Grindleford Bridge, Sheffield, in the County of Derby, England,

whose Post-Office address is Grindleford Bridge, Sheffield, in the County of Derby, England,

prays that Letters Patent may be granted to him for improvements in and relating to electric welding, (which he has divided out from his main application Serial No. 208034 filed 14th May 1904)

as set forth in the annexed specification.

And he hereby appoint s SPEAR MIDDLETON DONALDSON & SPEAR, (Ellis Spear, Frank L. Middleton, Walter Donaldson & James M. Spear,) of Washington D.C., Registration Number 6323, his Attorneys with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign the drawings, to receive the Patent, and to transact all business in the Patent Office connected therewith.

Signed at Sheffield England

this 16th day of December 1911

Sebastian Ziani de Ferranti

1324

TO ALL WHOM IT MAY CONCERN :

BE IT KNOWN THAT I, Sebastian Ziani de Ferranti, a subject of the King of Great Britain and Ireland, and residing at Grindleford Bridge, Sheffield, in the County of Derby, England, have invented certain new and useful "Improvements in and relating to electric welding" of which the following is a specification:-

668464
2

This invention relates to electric welding and is a divisional application from my patent application Serial No. 208034.

In electric welding as at present practised, it is customary to arrange that the weld is formed over the whole of the juxtaposed surfaces of the parts being welded. The amount of current required varies of course with the extent of the contacting surfaces, and when these are large the difficulty in forming the weld and the cost thereof increases.

In many cases ~~for example, in sheet metal work~~ to form the weld over the whole of the opposing surface would be quite unnecessary and out of proportion to the strength required, and I have devised a method by the employment of which welds of the desired strength can be obtained ~~in the above and other manufactures~~ in an exceedingly economical manner.

My invention consists in the improved processes and articles to be hereinafter described.

Referring now to the accompanying drawings,

Figure 1 shows an edge view of a turbine bladed element, the blades of which are welded in accordance with my invention.

Figure 2 is a part side elevation of the bladed element shown in Figure 1.

In carrying my invention into effect according to the form shown in the accompanying drawing, the turbine wheel or disc, a, has two intersecting sets of grooves, g, cut in the periphery thereof, so as to leave a series of projections, f, in the surface of the turbine wheel. The blade, d, is welded to certain of the projections, f, by passing across the points of contact

of the opposing surfaces, an electric current in a known manner.

It will thus be seen that on the completion of the welding operation the blades will be attached to the wheel or disc by a plurality of welds isolated from one another.

By my improved process it will be evident that considerable economy is effected in the cost of electrically welding the blade to the wheel or disc in comparison with methods at present in use.

I wish it to be understood that although I have described my invention as applied to the construction of a turbine wheel or disc, it is not limited to such, as it is of general application and may be applied in other circumstances where it is unnecessary or undesirable to form the weld over the whole of the contacting surfaces of the parts to be welded.

Having now described my invention, what I claim as new and desire to secure by Letters Patent is:-

1. A process for uniting two parts together consisting in utilising portions only of the individual juxtaposed surfaces for the transference of electric heating current so as to limit the heating effect of said current substantially to said portions and applying pressure so as to unite the parts by a weld of less area than that of the juxtaposed surfaces.

2. A process for uniting two parts together consisting in utilising portions only of the individual juxtaposed surfaces for the transference of an electric current the utilised portions being prepared so as to localise the heating effect of said current and applying pressure to unite the parts by a plurality of isolated electric welds.

3. A process for uniting two parts together consisting in leading an electric current across portions only of the individual juxtaposed surfaces of the parts and applying pressure to said parts so as to integrally unite the individual juxtaposed surfaces together by a plurality of isolated electric welds.

4. A process for uniting two parts together consisting in forming projections on one of the individual juxtaposed surfaces of said parts leading an electric current across the parts by way of said projections and applying pressure to unite the individual juxtaposed surfaces by a plurality of isolated electric welds.

5. A metal article having component parts thereof united by a weld of less area than that of the juxtaposed surfaces.

6. Composite metal articles having individual abutting portions united together by a plurality of isolated welds.

7. A metal article having a plurality of current localising portions formed on one of its surfaces.

WP/LW.

1028

In testimony whereof I have signed my name to this specification in the presence of two subscribing witnesses.

OATH.

AMERICAN CONSULATE
SHEFFIELD } ss.

SEBASTIAN ZIANI DE FERRANTI,

the above named petitioner being duly sworn deposes and says that he is a subject of the King of Great Britain and Ireland, and resident of Grindleford Bridge, Sheffield, in the County of Derby, England, that he verily believes himself to be the original, first, and sole inventor of the improvements in and relating to electric welding, (which he has divided out from his main application Serial No. 208034 filed 14th May 1904)

described and claimed in the annexed specification; that he do not know and do not believe the same was ever known or used before his invention or discovery thereof, or patented or described in any printed publication in any country before his invention or discovery thereof, or more than two years prior to this application, or patented in any country foreign to the United States on an application filed more than twelve months before this application; or in public use or on sale in the United States for more than two years prior to this application; and that no application for patent on said improvements has been filed by him or his representatives or assigns in any country foreign to the United States, except as follows: Great Britain No. 11921 filed 20-5-04, Switzerland filed 20-5-04, Austria filed 20-5-04, Germany filed 21-5-04, Belgium filed 26-5-04, Hungary filed 28-5-04, France filed 31-5-04, Russia filed 27/4/10/5/05, Canada filed 23-5-05, Japan filed 9-6-05 and Italy filed 27-7-05.

Paper No. 2.

WLR/KAJ

DEPARTMENT OF THE INTERIOR
UNITED STATES PATENT OFFICE
WASHINGTON Jan. 29, 1912.

S. Z. deFerranti,

Care Spear, Middleton, Donaldson and Spear,

City.

Please find below a communication from the EXAMINER in charge of your application.

668,464, filed Dec. 29, 1911----

Electric Welding.

E. B. Allen.
Commissioner of Patents.

Applicant calls this case a division of his application NO. 208,034, but it is found that this application page 2, lines 12 to 15, refers to welding sheets of metal together, face to face. There is no reference in the prior application to welding sheets, it being entirely limited to welding the ends of turbine blades to their carrier. For this reason this case is not a division of the prior case and is not entitled to the date thereof for the purpose of avoiding references.

Page 2, line 31, reference letter "f" is used but it is not found on the drawing.

Claims 5, 6 and 7 are for an article which is considered independent of an electric welding process such as set forth in claims 1 to 4 and they relate to a subject of invention which is separately classified from welding processes. Division is therefore required between claims 5, 6 and 7 and the remaining claims. It is not clear but that these claims are also barred in this application on account of applicant's patent 874,398. Dec. 24, 1907, Steam Eng. Rotary. There appears to be no line of division between these claims and claims in the patent.

668464

1330

Claims 1 to 4 are rejected upon each of the following patents-----

Wexham, 496,690, May 9, 1893, 219 - 10,
Kleinschmidt, 616,436, Dec. 20,1898, 219 - 10,
Hunter, 690,958, Jan. 14,1902, 219 - 10,

Fr. patent to Egel, 335,889, published Feb. 18, 1904, 219 -10

Fr. patent to Egel, 336,187, published Mar. 1, 1904, 219 - 10.

Since as stated above applicant is not entitled to the date of the prior application referred to these claims are also rejected upon Br. patent Harmatta, 22,981, of 1903, 219 - 10, or Rietzel, 928,701, Jul. 20, 1909, 219 - 10.

Wm. J. Rich
Examiner, Div. 3.

W

168704

Room 175.
S.Z.de Ferranti.
Serial No. 668464.
Filed December 29th,1911.
"ELECTRIC WELDING".

To the Commissioner of Patents.

Sir

This amendment is in reply to the Official letter of January 24th, 1913.

Page 2, line 11, erase "for example in sheet metal work"

lines 16 and 17, cancel "in the above and other manufactures"

As applicant has now erased the matter objected to by the Examiner as being not present in the parent application No. [illegible]4, it is respectfully submitted that the application as now amended is entitled to the date of the parent application.

Cancel claims 5, 6 and 7 at present on file.

With regard to claims 1 to 4 which the Examiner has rejected upon Meehan, Fleischmidt and Hunter, the applicant would respectfully point out that none of these citations appear to him to disclose a process of welding in which two parts are united together by a weld of less area than the juxtaposed surfaces.

With regard to Meehan's specification No.4[illegible]2, the applicant would respectfully point out that when the weld is finished according to the process in this specification, it extends over the whole surface of the juxtaposed surfaces. In evidence of this, attention is called to Page 1, line 31, where it is stated: "Figure 3 is a side view of a portion of a rail formed from the two abutting ends of rails shown in

Figure 2 after welding." In the applicant's article when finished, however, the juxtaposed surfaces are not united over their whole area by the resulting weld, but are united by a weld of less area than the juxtaposed surfaces.

In view of this important difference between Moxham's process and the applicant's, the applicant respectfully submits that the claims as at present on file are clear of this reference.

With regard to Kleinschmidt's specification No. 616436, the applicant would respectfully point out that in this case also the weld is formed over the whole of the juxtaposed surfaces, and on Page 1, a confirmation of this statement will be found at line 53, where it is stated that: "Figure 3 shows a cross-section of a completed weld between two spliced bars and the rail taken on a line which would pass through one of the bosses b." From the figure it will be evident that the weld extends over the whole of the juxtaposed surfaces, and accordingly the applicant submits that the claims as at present on file are clear of this reference also.

With regard to Hunter's specification No.690958, the applicant would point out that in this case the projections which are formed before welding, are melted off so that the molten metal spreads over the whole surfaces of the overlapping portions, and forms a complete weld, and Page 1, line 56, is cited as showing that a whole weld is formed between the overlapping surfaces, which states: "and as the metal in the immediate vicinity of the projections on the two plates melts, small lakes of molten metal are formed which quickly spread and unite, making a full transverse weld."

It is evident from the processes disclosed in these three specifications, that in none of them is there any disclosure of the applicant's invention, as in each case it would appear that the whole of the juxtaposed surfaces are welded together. The applicant, however, unites the two parts together, not over the whole of the juxtaposed surfaces, but by a weld having an area of less extent than that of said surfaces. By this method he is enabled to weld two parts together by a series of welds which economize the amount of electric current used, and can be so arranged as to give the desired strength of weld.

In view of the great importance of this form of welding and the economy which it effects in the current, it will be evident that the applicant has effected a material advance upon the state of the art cited by the Examiner, and for this reason respectfully requests a reconsideration of the case.

Would the Examiner be good enough to insert the reference letter "f" in the drawing to designate the projections to which the blades, d, are welded.

With regard to the French patents to Egel, and the British patents to Haramatta, and Rietzel, the applicant would respectfully point out that as he has now eliminated from his specification the matter objected to by the Examiner as not contained in the parent application, he respectfully requests that these reference be discarded, as he claims the date of his British Patent Application, viz., May 25th, 1903, which is prior to the dates of these references.

Early allowance of the case is respectfully requested.

FILED

[illegible] from the EXAMINER in charge of your application.

648,464 , filed Dec. 29, 1911---

Electric Welding.

E. B. Moore

Commissioner of Patents.

Replying to amendment filed Dec. 31, 1912.

Applicant has canceled the reference to the welding of sheet metal. This, in connection with the fact that the original case serial number 208,034, was limited exclusively to the welding of turbine blades, may be taken to warrant the position that the present claims in this case are either not warranted or must be construed to be for a different principle and process from that involved in the Rietzel and Marmetta case. The claims, therefore, while taken in the terms expressed, as broad enough to include these processes, are actually not considered to relate to the same type of process. They should be revised in this repsect so as to bring out more clearly the idea involved in applicant's original disclosure, that is of the welding of two massive pieces of metal together but with surface contact less than the cross section of the pieces. Taken in this light the claims appear to be fully met by----Moxham, Kleinschmidt and Hunter of record. The patent to Perry, 576,039, Jan. 26, 1897, 39, Fences. Sub. 72, also meets the terms of these claims. The statement in applicant's remarks that the metal spreads over the whole surface

by

in Hunter's process
of the overlapped portions/is not considered accurate. It is thought that the welding portion would form a line or strip of less extent than the whole area of the overlapped portion.

Applicant's attention is called to the fact that if he wishes to rely upon the date of a foreign application that such application must be proven by filing a certified copy of the application as filed, ex parte Pauling, 1905, C.D., 131.

Wm. F. Rich
Examiner Div. 3.

Serial No. 668464
Paper No 6 Amendment B

Room 175.
S. Z. de Ferranti.
"ELECTRIC WELDING".
Serial No.668464.
Filed December 29th, 1911.

To the Commissioner of Patents.

Sir,

This amendment is in reply to the Official letters of January 18th,1913, and March 7th, 1913.

Applicant files herewith a certified copy of the British specification No.11921 of 1903, showing the Provisional Specification as filed on the 25th of May 1903, the date which the applicant claims under the International Convention.

Claim 4, line 2, after "on" insert "one of"

Insert the following claims:-

B'

5. A process of uniting two parts togethe consisting in forming one of the juxtaposed surfaces of said parts with relatively raised and depressed portions and leading an electric current across the parts by way of said raised portions and applying pressure to unite the juxtaposed surfaces by a plurality of isolated electric welds.

6. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localised in such spots.

7. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-

668464

-1-

defined areas of no union, consisting in applying pressure localised at the spots of desired union and passing electric current through the pieces from one to the other, while confining the flow of current to said spots until the union is effected.

8. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localising the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

9. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together and passing a welding electric current from one to the other while localising the pressure in and confining the flow of current to the spot or spots of desired union, so as to produce an isolated spot or spots of union leaving distinct or well-defined areas in which the pieces are not welded together.

Claims 6 to 9 are claims 1 to 4 from Patent Specification No.1,046,066 to Harmatta, and the applicant respectfully requests that an Interference be declared with Harmatta, in order to decide the priority of the invention as stated in the above claims.

Respectfully,

PROVISIONAL SPECIFICATION.

"Improvements in and relating to the Electric Welding of Turbine Blades."

I, SEBASTIAN ZIANI DE FERRANTI, Engineer, of 41, Lyndhurst Road, Hampstead, London, N.W., do hereby declare the nature of this invention to be as follows:—

The invention relates to improvements in methods of electrically welding of turbine blades to the discs or drums carrying them, and has for its object to overcome the difficulties which have been experienced in electrically welding together the two parts which differ considerably as regards their power of rising to the required welding temperature when heated at the point of junction.

The main difficulty arises through the blades and their carrying discs differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the disc, ring or the like to which it is to be secured it is found that the comparatively large volume of metal forming the disc rapidly conducts heat away from the welding point, thus preventing the temperature of the disc part rising to the required extent and causing an unsatisfactory weld.

The invention therefore consists broadly in adjusting the volume of metal of the disc in the neighbourhood of the welding point so that approximately equal heating occurs in both faces to be welded, whereby turbine wheels with welded blades may be reliably produced in an inexpensive way.

In carrying out my invention according to one modification grooves may be cut across the edge of the ring or several grooves may run circumferentially completely round the edge, or again intersecting sets of grooves inclined to one another may be cut on the edge of the ring.

According to another modification, radial holes may be bored a short distance into the edge, either arranged in patterns so as to leave intervening projections or untouched metal to which the blades may be welded or arranged with no particular reference to the position of the blades.

The object to be kept in mind in this as in other modifications is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Again, the result aimed at may be secured by boring holes through from face to face of the ring at a radius slightly less than that of its outside edge.

According to another modification of the invention, the ring may be built up of two or more thinner rings held in their relative positions by distance pieces or in any other convenient manner, the blades being then welded in position on their outside edges.

Again, the ring may be built up of a set of thin laminæ, the edges of which are notched, the laminæ being assembled in such a way that the notches

COMPLETE SPECIFICATION.

"Improvements in and relating to the Electric Welding of Turbine Blades."

I, SEBASTIAN ZIANI DE FERRANTI, Engineer, of 31, Lyndhurst Road, Hampstead, London, N.W., do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:

The invention relates to improvements in and relating to methods of electrically welding turbine blades to the discs, drums or the like carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an inexpensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier rapidly conducts heat away from the welding point, thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of the blade carrying element in the neighbourhood of the welding point, so that approximately equal heating occurs in both faces to be welded.

Referring to the accompanying drawings which, with the exception of Figure 4, show the invention applied, by way of example, to a type of parallel flow turbine in which the blades are mounted on the edge of a wheel-like body,

Figure 1 is a part side elevation of such a wheel having cross grooves,

Figure 1ª being an edge view;

Figure 2 shows a similar edge view of a modification in which sets of inter...ecting grooves are adopted;

Figure 3 shows an edge view of a form having circumferential grooves,

Figure 3ª being a section on the line A B of Figure 3;

Figure 4 shows, in longitudinal sectional elevation, part of a drum carrier to which the blades are welded in accordance with one form of the invention;

Figures 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disc, while

Figure 7 is a part side elevation in which holes are bored through from face to face of the disc;

Figure 8 shows a sectional plan of a form of wheel built up of two dished discs, held apart at their circumferential portions by distance pieces,

8464
21

OPY

Figure 8ª being a scrap edge view to a larger scale;

Figure 9 is a similar sectional plan of a modified form of wheel built up of three discs, while

Figure 9ª is a corresponding scrap edge view also to a larger scale:

Figure 10 shows a part sectional elevation of a wheel built up of two comparatively thick discs having notched edges.

Figure 10ª being a scrap edge view, while finally

Figure 11 shows an edge view of a form of wheel built up of a series of "stepped" laminæ.

It will be seen that all the edge views are shown as developments for clearness of drawing and not as true projections.

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

In carrying out the invention according to the form shown in Figures 1 and 1ª, the turbine wheel or disc is shown at *a*, cross grooves, *c*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded.

The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disc, as is shown in Figure 2, or by cutting circumferential grooves, such as *f*, completely round the edge (see Figures 3 and 3ª.)

Figure 4 shows the invention, according to one form, applied to the case of a drum blade carrier, *a*¹; the drum is grooved circumferentially with grooves, *f*¹, the intervening collars of metal being then cross-cut to form projecting teeth, *c*¹, on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disc, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in Figure 5, or arranged without particular reference to the position of the blades, (see Figure 6).

In Figure 7, a method is shown of removing metal in the neighbourhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disc at a radius slightly less than that of its outside edge.

The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, whilst at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Referring now to Figures 8 and 8ª, a form of wheel is shown somewhat diagrammatically which is built up of two dished discs, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as *l*, disposed at a radius somewhat less than the maximum radius of the discs, the blades, *d*, being welded in position on their outside edges.

Figures 9 and 9ª show a type of wheel generally similar to that last described but having an intermediate plate disc *m*, in addition to the two dished discs, *k*: a portion, *n*, of the hub, *o*, in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the discs in their correct relative position may be adopted.

In Figures 8 and 9, the dished discs, *k*, are indicated as secured to the hubs, *o*, by pressing the inner edges of these discs into grooves and subsequently [illegible] over the hubs to hold the discs in place.

In the modification shown in Figure 10 and 10ª two dished discs, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to Figures 1 and 1ª.

Again, that portion of the disc carrying the blades, may be built up of a set of discs, similar to, say Figure 11, the edges of which are notched as at *s*, the pieces being assembled in such a way that the notches, *s*, are "stepped"

with regard to each other, and that the intervening projections of metal may follow the shape of the turbine blades to be united to them.

Instead of welding the laminæ, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In an invention such as the present, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the same is sufficiently indicated by the many examples given above, and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

Having now particularly described and ascertained the nature of the said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. In turbines, the method of welding the turbine blades to the elements carrying them, consisting in so adjusting the volume of metal in the blade carrier in the neighbourhood of the welding point, that approximately equal heating occurs in the two parts, substantially as described.

2. In turbines, blade carrying elements having blades welded thereupon in accordance with the method claimed in Claim 1.

3. In turbines, grooving the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

4. The bladed turbine element, hereinbefore described with reference to Figures 1 and 1ª of the accompanying drawings.

5. The bladed turbine element, hereinbefore described with reference to Figure 2 of the accompanying drawings.

6. The bladed turbine element, hereinbefore described with reference to Figures 3 and 3ª of the accompanying drawings.

7. The bladed turbine element, hereinbefore described with reference to Figure 4 of the accompanying drawings.

8. In turbines, forming holes in the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

9. The bladed turbine elements hereinbefore described with reference to Figures 5 and 6 of the accompanying drawings.

10. The bladed turbine element, hereinbefore described with reference to Figure 7 of the accompanying drawings.

11. In turbines, welding the blade carriers of comparatively thin parts across the non-touching edges of which the blades are welded, substantially as described.

12. The bladed turbine element, hereinbefore described with reference to Figures 8 and 8ª of the accompanying drawings.

13. The bladed turbine element, hereinbefore described with reference to Figures 9 and 9ª of the accompanying drawings.

14. The bladed turbine element, hereinbefore described with reference to Figures 10 and 10ª of the accompanying drawings.

15. In turbines, building the blade carriers of prepared laminæ assembled in a "stepped" manner, substantially as and for the purpose hereinbefore described.

16. The bladed turbine element, hereinbefore described with reference to Figure 11 of the accompanying drawings.

Dated this 27th day of February, 1904.

Herein find letter [illegible] of a communication from the Examiner concerning the application of Sebastian Ziani de Ferranti, for Electric Welding, filed Dec. 29, 1911, Ser. No. 668,464.

Very respectfully.

Form No. 175

E. B. Moore
Commissioner of Patents.

67709

The case, above referred to, is adjudged to interfere with others, hereafter specified, and the question of priority will be determined in conformity with the Rules.

The statement demanded by Rule 110 must be sealed up and filed on or before DEC 1 1913, with the subject of the interference, and marked with the number of the interference, indorsed on the envelope. The subject-matter involved in the interference is

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

689,464
3C

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

The interference involves your application for Electric Welding, application above identified and a patent/granted to Johann Harmatta whose post office address is Szepesvaralja, Austria-Hungary, whose assignee is the Thomson Electric Welding Co., Lynn, Massachusetts and whose attorney is O. F. Duffy abd Son, 612 F. St., N.W., Washington, D.C.

The relation of the counts of the interference to the claims of the respective parties is as follows:---

PETITION and POWER.

To the Commissioner of Patents,

UNITED STATES of AMERICA.

Your Petitioner Johann Harmatta Engineer, a subject of the King of Hungary residing at Szepesvaralja, in the Kingdom of Hungary prays that Letters Patent of the United States be granted to him for the Improvements in Electric Welding set forth in the annexed specification:

And he hereby appoints Messrs Marion and Marion (J.A.Marion & J.Wilfrid Marion)of Montreal, Province of Quebec, Canada, and Washington, D.C., U.S.A., his Attorney with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign his name to the drawings, to receive the Letters Patent when issued, and to transact all business in the Patent Office connected therewith.

Signed at Budapest, Hungary this 5th day of November, 1903

Johann Harmatta

Address Communications to
MONTREAL OFFICE

Specification.

To all whom it may concern:

Be it known that I, Johann Harmatta, Engineer, a subject of the King of Hungary, residing at Szepesvaralja, in the Kindom of Hungary, have invented new and useful "Improvements in Electric Welding", of which the following is a specification.

My invention relates to a process of and apparatus for manufacturing metal articles of all kinds, in particular those of the thinnest sheet metal, by direct electric welding. The new process consists in one of the electrodes (or both of them) not only serving to feed the current, but also being employed for exercising a more or less strong pressure either before and during the period of supplying the electric current, or only at the moment of this supply, at the place at which the welding is to be done. The member which feeds the electricity is thus at the same time the tool, and in this manner the most favorable con-

Canceled-per Sub.-Spec.-May-14,-1904.

Sub. K[1]

ditions of working possible are secured, since, as is well known, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough.

According to none of the present known electric welding processes are the articles to be welded firmly pressed together during the welding operation by one or both electrodes, for the purpose of favoring welding. Hitherto either no pressure has been exerted at all, or it has been exercised at a certain distance from the place of welding, or at all events not centrally direct upon the electrodes pressing on the place to be heated. In short, hitherto direct electric welding pressure has never been exercised by means of the electrodes located in the direction of the current directly above the surface or point being welded.

For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place of welding by the aid of any of those technical means which are suitable for producing or transmitting pressure; e.g., with a press either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power.

In the accompanying drawing

Fig. 1 is a view illustrating the welding of

two metal sheets of equal thickness, intermittently or at certain spots only.

Fig. 2 is a front elevation and

Fig. 3 a side elevation of a device which may be employed for continuous welding, the pressure being exerted by roller electrodes, whereby the advancing series of single points of the seam to be welded is united to a whole with a minimum consumption of current.

Fig. 4 illustrates the method of welding the longitudinal seam of a cylindrical or conical hollow article according to my new process.

Fig. 5 is a side elevation of a welding device (also illustrated in part in Fig.1) according to which the pressure is exercised by pin shaped electrodes, the form of which may be suited to the particular purpose in view, and which may be adapted to work on the smallest possible surface of contact.

Fig. 6 shows two forms which may be adopted for the ends of the contacting electrodes.

As Fig. 1 shows, the two sheet metal or other bodies, the edges of which lie upon each other, are introduced between the two electrodes a b. Of the latter the one, somewhat prior to welding or only during the welding operation, is pressed upon the other, as the arrow shows; or both electrodes may be caused to exert pressure on the objects to be welded.

For continuous welding of longitudinal, cross and circular seams, the device shown in Figs. 2 and 3 of the drawing may be advantageously employed.

In the two conductors c d (Fig.3), forked members e f, making intimate contact with the conductors, are introduced, each furnished with a removable roller electrode g and h; or, if desired, only the lower roller electrode, for instance, may be capable of being removed. Or the lower or upper electrode may be formed as movable roller and the other electrode forms a stationary conductor.

The roller g of the upper conductor c is keyed to an axis i carrying a spur wheel k to which the motion of a suitably mounted hand-wheel l can be transmitted by means of a spur wheel m. Or the hand-wheel may be mounted directly on the shaft g, without the use of any intermediate gear-wheels. Or the axis i may have on the other end also a spur or bevel wheel, or pulley or the like for driving the roller electrode g, should it be desired to automatically advance the object being welded by means of motor power. The purpose of the hand-wheel is to accelerate or decrease the speed of rotation of the roller g, as may be required, and in general to actuate the roller by hand for any purpose. The axis i may, of course, be caused to move slower or faster in the case of mechanical power, by any other suitable means. The

upper part of the fork carrying the electrode roller g is here shown as constituting a toothed rack n, in which engages a pinion p carried by the conductor c by means of a ring-holder o. The pinion p is keyed to the axis q, which carries a hand lever r at its outer end. By raising or depressing the lever r, the upper roller electrode g may be separated from or advanced towards the lower roller electrode h. Furthermore by raising or depressing the forked piece f in the conductor d the lower removable roller h may be adjusted higher or lower.

If now the ends of the objects to be welded are introduced between the two roller electrodes g h and the circuit closed, continuous welding may be undertaken, that is to say an uninterrupted welded seam made, whereby the upper rotary roller electrode g may be pressed with any required degree of pressure upon the lower stationary (or rotary) roller electrode h, so that the two ends of the material to be welded are firmly connected with each other.

Instead of the objects to be welded being introduced gradually between the electrodes, the electric welding apparatus may be arranged to slide relatively to the stationary objects.

Thus if it is required to weld, for instance, sheets of metal only at particular places, the apparatus shown in Fig. 5 may be advantageously employed,

the electrodes a b having the form of pins. The lower electrode b is then inserted in the conductor d, whilst the upper electrode a is carried by an arm e by means of a hand-lever t carried by said arm e and can be turned on the shaft u in such manner that the points of the electrodes a b approach and recede from each other. If then two superposed sheet metal ends to be welded together are introduced between the electrodes, and the latter then firmly pressed together and the circuit closed, a small round, very sharply defined place of welding is caused which perfectly answers the purposes of a rivet. In this event, also, especially in the case of thin vessels which are not required to withstand great pressure, the pressure on the place of welding may act at the right moment be exactly regulated or kept within the proper limits.

11 words interlineated

Having thus described my invention, what I claim as new and desire to secure by letters patent is :-

1. The process of electric welding, consisting in employing the electrodes not only to conduct the current to the objects being welded, but also to exert a regulable pressure on the same, substantially as described.

2. An electrode apparatus for electric welding, comprising two electrodes between which the objects to be welded are introduced, and means whereby one of the

electrodes can be approached to and receded from the other, substantially as described.

3. An electrode apparatus for electric welding comprising two roller electrodes between which the objects to be welded are introduced, and means for pressing the electrodes to the work, substantially as described.

4. An electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, means for pressing the electrodes to the work, and means for rotating one or both of the rollers for the purpose of advancing the work in its path between the electrodes, substantially as described.

In Witness whereof I have hereunto signed my name this 5th day of November, 1903, in the presence of two subscribing witnesses.

Please find below a communication from the EXAMINER in charge of your application.

#183,677, filed Dec. 3, 1903, for Electric Welding.

F. I. Allen. Commissioner of Patents.

6—2031

The statements beginning in line 6, page 2, should be amended or canceled in view of the references to be hereinafter cited.

Division is required in this case as between claim 1 which is drawn to cover a process, and the remaining claims which cover an apparatus. Claim 1, however, does not appear to be a proper process claim but simply covers the functions of the apparatus. If this claim is retained in its present form the requirement for division will be insisted upon. The statement of invention should be made to conform to whichever subject matter is covered by the claims retained in the case.

Claim 2 is rejected on eachof the following patents:

Burton et al.,	486,626,	Nov. 22, 1892,
Burton,	647,694,	Apr. 17, 1900,
Anderson,	657,262,	Sept. 4, 1900,
Duncan,	660,152,	Oct. 23, 1900,
Perry,	670,808,	Mar. 26, 1901, Metal Working, Electric.

Claims 3 and 4 are rejected on Burton et al., cited. To apply the power directly to the shaft upon which the roller electrode is supported, does not involve invention.

APPLICATION OF JOHANN HARMATTA,
ELECTRIC WELDING,
FILED DECEMBER 3,1903, SERIAL NO. 183,677. } AMENDMENT

HON. COMMISSIONER OF PATENTS,

WASHINGTON, D. C.

SIR:-

Referring to the Office action of January 9th, 1904, we hereby amend as follows:

Cancel the entire specification and claims with the exception of the preamble and signatures, and insert the following.

Sub. Spec.

May 14, 1904.

per A

The subject of my invention is a process of welding thin sheet metal by means of electricity.

As is well known, it is impossible, by means of the ordinary methods of electric welding, to produce a really sound seam between very thin metal from about two millimeters in thickness downward sheets, that is to say, a seam which is perfect at every part, without there being any fusing or burning away of the material being welded.

The reason of this I have ascertained to be as follows:-

On the ordinary systems of welding it is the practice at once to lead a current to the objects to be welded (such as iron bars, hoops, chain links, or the like), whereby, in consequence of the thinner or thicker layer of air, which is always present between the two objects, vigorous sparking occurs. There is, so to say, a line of sparks or an arc formed, which persists until the objects being welded have been brought to welding heat by the electric current, whereupon they are finally pressed together to effect the desired union.

This well-known method, therefore, does not really differ from the ordinary method of welding

at the fire, except that instead of the gases of combustion of the fuel, the electric current is employed to heat the bodies to be welded. Once the welding heat is reached, however, the final union of the bodies in either case is effected by mechanical pressure (pressing or hammering).

For the purpose of enabling my invention to be more readily understood, I will make reference to the accompanying drawing, in which

Fig. 1 is a sectional view illustrating the electric welding of two comparatively thick sheets on the ordinary system.

Erased per C

Fig. 2, is a like view showing what occurs when one of the sheets is thin.

per C

Fig. 1 is a section of portions of two thin sheets with an air-gap between them.

" Fig. 2 is a sectional view illustrating the employment of my new process in welding thin sheets.

" Fig. 3 is a like view showing the welding of the overlapping ends of two pieces of sheet metal.

" In known processes

" As Fig. 1 shows, the electrodes A B lie opposite each other, the sheets X, Z to be welded by the ordinary process being located between them. The sheets lie loosely upon each other, that is to say, they are not artificially pressed together, and the consequence is that, that they are separated by a layer of air 3.

If now the electric circuit is completed

through the two electrodes and the sheets, and if the layer of air 3 is sufficiently thick, that is to say, the air resistance sufficiently great, there will be no sparks or arc formed between the two plates for the time being. If, however, the sheets are approached, as is unavoidable for the purpose of final union by pressing, hammering, etc., as already explained, a time must arrive when the air resistance between the two sheets to be welded is no longer sufficiently great toprevent equalisation of the electricity at the two poles. Between the sheets, therefore, an arc or a line ofsparks will be formed, and will continue until intimate contact has taken place between the two sheets. If, as is shown in Fig.1, the sheets are relatively thick, the arc which is formed will be of no consequence, since the slight fusing away at 4 caused by the arc, or the sparks, will not be sufficiently deep to penetrate the thick material. In fact there is even an advantage in the action of the sparks or arc in the case in question, since the cross section of the material is altered, whereby the two sheets are, as it were, scarfed at the place of welding, that is to say, the two cross sections are dimished at the seam toapproximately the thickness of a single sheet, so that under certain conditions the two welded sheets have the same thickness at the joint as a single sheet.

1370

The case is altogether other when two thin sheets or articles are to be welded, or when a very thin object is to be welded to a thicker one, such as is shown, for instance, in Fig.2. In this Figure it is assumed that the thick sheet 2 (which, as explained with reference to Fig.1, is thick enough not to be penetrated completely by the arc at the point 4) is to be electrically welded to a very thin plate 5 by the ordinary process as above explained.

On the approach of the objects 2, 5, at a certain moment, in consequence of the penetration of the layer of air 3, fusing away takes place at 4, owing to the arcs or sparks, and this fusing will extend tosuch depth that, although, as as above explained, not injurious in the case of the sheet 2, it causes the thin sheet 5 to be completely perforated or burnt through. Thus the ordinary process of welding by means of an arc is quite impracticable with such thin sheets.

per A

The essential feature of my invention i s that from about two millimeters in thickness downward in welding thin sheets the formation of such an arc, or sparking distance, which proves so disastrous, is wholly avoided, whereby a perfectly sound welded joint between such bodies, or between a very thin body and a thicker object, is attained.

For the purpose of preventing the formation of the injurious arc, that is to say the sparking

distance, I first submit the superposed metal objects to be welded 5, 6 (Figs. 4 & 5) to a certain pressure, the amount of which will depend upon the nature of the said objects. This pressure I effect by means of the electrodes a b (Figs. 4 & 5) themselves, or with the aid of other suitable means. The purpose of this pressure is to bring into intimate contact the parts of the metal to be united, so that the layer of air between them is as far as possible expelled. In this manner the two parts to be welded are, as it were, mechanically connected to form a single homogeneous body. This is of great importance when the two very thin sheets are to be welded together. For, as is well known, thin sheets have always a more or less wavy form, so far as they have not been straightened in the process of manufacture so as to present a surface which is practically quite flat, such as is the case with thick sheets. Such thin sheets, therefore, unless submitted to mechanical pressure never lie close upon one another; on the contrary, in consequence of the waved form, large air-gaps 3 (Fig. 3) are left between them, so that if a current were led through them, it would aid sparking and the formation of arcs.

After the two metal objects have, therefore, been prepared in this way, that is to say, by the application of mechanical pressure caused to lie closely upon each other, without any air-gap, between

them, the electric circuit is closed, the mechanical pressure being still maintained.

At the place where the electrodes a b exert pressure, therefore, (Figs.4 & 5), that is to say, where the current is able to flow through the bodies to be welded without having to pass through a layer of air and form sparks, the metal is heated to welding heat. Immediately this temperature is reached, the continuous pressure effects the desired union, that is to say, welding of the two metal objects 5 and 6, without injury by perforation or burning, in the manner explained, having taken place, even if the sheets are extremely thin. It should be remarked that the pressure to be exercised on the bodies before and during welding, must be selected according to the thickness of the sheets, and can be adapted to suit the condition of the bodies for the time being. Thicker sheets or objects do not require so much pressure as thin ones because, as already explained, they have a more even, uniform shape and therefore when laid upon each other can be readily closed together, that is to say pressed so that no injurious air-gap is formed.

Since the essential condition is, that the two metal objects to be united are firmly pressed together before welding, in order that complete penetration of the thin body by the electric current may be avoided, it is obvious that with this process

not only two equally thin sheets, but a very thin sheet and a thicker metal object may be welded without danger of the former being burnt through.

Naturally the required super-ficial pressure may be exerted by only one electrode, or by both the electrodes.

Having thus described my invention, what I claim as new and desire to secure by Letters Patent is:-

The process of electrically welding thin sheets and the like, consisting in applying pressure at the place of welding of the two superposed metallic objects to be united, for the purpose of effecting thorough superficial contact between them, and then, whilst maintaining the said pressure, heating the objects by passing an electric current through them, substantially as described.

Sub. A1

Cancel the drawing originally filed and substitute the one accompanying this specification.

REMARKS.

It is hoped that this amendment will place the application in condition for allowance.

RESPECTFULLY SUBMITTED,

Marion & Marion

ATTORNEYS.

"Improvements in Processes of Electric Welding".

Ser. No. 183677; filed Dec. 3, 1903.

Hon. Commissioner of Patents,

W a s h i n g t o n D. C.

Sir.-

Erase the claim and substitute the following:

A1
Sub. B

1. The process of electrically welding thin metallic sheets and the like, from about two millimeters in thickness downward, consisting in first pressing intimately together the two superposed metallic objects at the very point in which the welding joint is to be formed, and then, whilst maintaining the intimate pressure, heating the objects by passing an electric current through them exactly at said point, in which the welding is to be effected, substantially as set forth.

2. The process of electrically welding thin metallic sheets and the like from about two millimeters in thickness downward, consisting in superposing the metallic sheets and the like, exerting on said thin sheets and the like before and during the welding operation a pressure limited to a material point, and passing for a short moment a current also limited to said material point through said thin sheets and the like, substantially as set forth.

3. The process of forming seams with thin sheets and the like from about two millimeters in thickness downward, consisting in pressing together the parts to be welded in a series of points consecutively, and, whilst maintaining the pressure in said consecutive points, passing an electric current for a short moment exclusively through said points, substantially as set forth.

In sert "from about two millimeters in thickness downward" after "sheets" on page 1, line 6 from above, and on page 4, line 7 from below.

R e m a r k s :

The process described in the U.S.Patent No. 758,503 to B l e v i n s and W i t t a k e r differs essentially from the process forming the object of the present aplication No. 183,677. In the process of B l e v i n s and W i t t a k e r namely, the inventors intend to weld a great surface, for example

a whole annular surface or a seam, in one stroke. On the contrary, the applicant desires only to weld the parts together in material points, so that a seam is formed by a series of welded points. Now, in the process of B l e v i n s and w i t t a k e r an enormous amount of current is necessary, so that the latter process is not fit for practical purposes. On the contrary, the process of applicant is very economical and only necessitates a small amount of current, because the heating at the place to be welded is still limited to a material point. Further, in the process of B l e v i n s and W i t t a k e r, owing to the great amount of current used, not only the surfaces to be welded, but also the neighbouring places are heated, so that a great electrical resistance is produced, which increases during the heating, as stated in page 2, line 20 and 21 of the specification, Consequently, B l e v i n s and W i t t a k e r are obliged to use a current regulator (variable resistance or rheostat) in order to be able to gradually increase the current during the welding operation, so that a complicated plant is necessary. Now, in the process of applicant, the use of a current regulator or rheostat is not necessary, because no great change in the electrical resistance takes place during the welding. A change in the strength of current is only necessary when other materials or sheets than before are intended to be welded, but during the welding operation the strength of the current used remains constant.

Furthermore, in the process of B l e v i n s and W i t t a k e r the inventors cannot have taken in consideration that, when thin metallic sheets from about two millimeters in thickness downward are to be welded together, it is absolutely necessary that the surfaces to be welded be in intimate contact, before the electrical current being led in. However, it is quite impossible to press together in one stroke two great surfaces (for example annular surfaces) so perfectly that no small hollow places at all remain, which, as is well known, always give rise to the production of small electrical arcs and consequently to a fusing away or burning through of the thin material at the welding place. Therefore, applicant before the welding operation proper affords a very intimate contact between the superposed objects to be welded, but only in material points, several consecutive points forming a line in the case of seams. Now, as B l e v i n s and W i t t a k e r produce the contact between relatively great surfaces and not only in points, a fusing away or burning through of the thin metallic sheets must always take place, inasmuch as the regulation of the strength of current, that is the fact of letting in a stronger current during the welding, is of a dangerous or injurious character, that is, is often connected with a spoiling or burning through of the thin materials. For welding together thin metallic sheets a quite determined temperature is necessary, which must not

be exceeded, and the heating must only last a short moment, or else the material is fused away or burnt through. In a few words for welding together thin sheets, the heating must be limited to a point and to a very short moment, if really practical results are to be obtained, and the process of applicant is based upon these considerations.

In order to show the favourable results obtained with the new process the applicant is ready to have the process demonstrated and experiments made before the Examiner at the Patent Office in Washington D.C.

An allowance of the new claims or a notice telling if experiments are thought to be necessary is requested.

Very respectfully,

Marion & Marion

J o h a n n H a r m a t t a,
c/o M a r i o n & M a r i o n, Montreal, Canada.
"Improvements in Processes of Electric Welding,"
Ser. No.183677, filed Dec. 3rd, 1903. ROOM 107.

Hon. Commissioner of Patents,
W a s h i n g t o n D.C.
Sir:----------

Responsive to the Official action of March 30th, 1908, in the above entitled application, amendment is hereby made as follows.

The applicant does not merely make the electrodes of a suitable size in order to adapt the same to the welding of sheets of very thin material (from about two millimeters in thickness downward), but by his method of welding such sheets of very thin material (from about two millimeters in thickness downward) he solved a problem which until now was considered as quite insoluble.

The U.S. Patent No.496,019 but relates to an improved method of producing soldered joints. Now, as in the process forming the object of the present invention no solder or uniting metal is used, the process described in the U. S. specification 496019, according to the opinion of applicant, cannot be opposed with right to the invention's object.

Further, the method described in the U. Specification No.444928 quite differs from the process forming the object of the present application. In the method disclosed in said U. S. specification No.444928 there is no question of affording a quite intimate contact between very thin sheets of iron, before the electric current is led to said sheets so as to weld the same together. In said method forming the subject matter of the U. S. patent No.444928 the pressure is only used in order to complete the welding process after the heating of the materials has taken place, but, exactly like in the ordinary welding with the use of a smithy fire, no pressure is exerted upon the sheets or the like at the very first stage of the process. On the contrary, in the process of applicant the pressure is in advance with regard to the welding action of the electric current from the beginning and also during the whole duration of the process.

Furthermore, it is quite certain that never welding trials with very thin sheets of metal - for example of 0.3 mm thickness - have been effected according to the process of the U. S. patent No.444928. If such trials had been made by Thomson before the application of his U. S. Patent some hints as to the absolute necessity of intimately pressing together plates of very thin metal from the beginning before the welding operation proper should have given in said U.S. specification No.444928, because, if one does not

proceed in this way, a burning through of the thin materials to be welded is unavoidable. It is true that Thomson has provided pressing means, but he does not use said means in the same manner as applicant and besides not for pressing together very thin metal sheets from about two millimeters thickness downward.

The inventor was occupied during quite a number of years with the electric welding and tried to weld together very thin sheets also with the help of the principles stated in the U.S.Patent 444928, but he obtained no practical results. Sometimes only an apparently good welding was obtained, but in the majority of cases the thin materials were burnt through and showed holes like a sieve, said holes being produced by electric sparks generated between the metallic surfaces in imperfect contact, and if a welding of such thin sheets could be obtained at all, the material was very much weakened at the place welded, so that said materials could not be used for practical purpose.

Only after long and repeated experiments the inventor, which during its trials found that a heating of the thin materials before the welding operation proper, that is before the leading in of the electric current, must be avoided under all circumstances, discovered a way or method which permits a welding together of such thin sheets being effected with absolute certainty and reliability i. e. without a failure being possible.

It is quite true that with the devices of Thomson the eventual possibility existed to work in the same manner as applicant, but as a matter of fact nobody has worked in the same way as applicant and no one before applicant was able to weld so very thin metal sheets together with absolute reliability, that is without a burning through or damaging of the very thin metallic sheets being possible.

It is quite remarquable that in all the specifications cited by the United States Patent Office there is only question of the electric welding of objects which can also be welded in an ordinary smithy fire, but in said former specifications absolutely nothing is said about the electric welding of very thin sheets of metal which can also not be welded in the fire of a smithy. Therefore the applicant is entitled to believe that no one before him devoted his attention to the welding of thin sheet of metal from about two millimeters in thickness downward, specially on an industrial scale. Consequently, nobody before the applicant was able to discover the fact than in welding very thin metallic sheets, the pressure must still be in advance with regard to the welding.

Besides, please strike the former claims and substitute the following, which are exactly limited with regard to the processes and objects already known:

Sub. C[1]

1. The process of electrically welding thin metallic sheets and the like, from about two millimeters in thickness

downward, which cannot be welded in the fire of a smithy, consisting in first pressing intimately together the two superposed metallic objects at the very point, in which the welding joint is to be formed, and then, whilst maintaining the intimate pressure, heating the objects by passing an electric current through them exactly at said point, in which the welding is to be effected, substantially as set forth.

2. The process of electrically welding thin metallic sheets and the like from about two millimeters in thickness downward, which cannot be welded in the fire of a smithy, consisting in superposing the metallic sheets and the like, exerting on said thin sheets and the like before and during the welding operation a pressure limited to a material point, and passing for a short moment a current also limited to said material point through said thin sheets and the like, substantially as set forth .

3.The process of forming seams with thin sheets and the like from about two millimeters in thickness downward, which cannot be welded in the fire of a smithy, consisting in pressing together the parts to be welded in a series of points consecutively, and, whilst maintaining the pressure in said consecutive points, passing an electric current for a short moment exclusively through said points, so as to keep the pressing action in advance of the electric heating during the whole welding operation, substantially as set forth.

13565

Favourable reconsideration and an early allowance is requested.

Very respectfully

Marion & Marion

#183,677, for Electric Welding, filed Dec. 3, 1903.

F. I. Allen

Commissioner of Patents.

This is in response to the amendment filed Nov.17,1905.

Figures 1 and 2, which are for the purpose of illustrating what is old in the art, should be canceled and the description accordingly revised,- ex parte Wadsworth, 92 O.G., 1898. The description should be confined to applicant's process of welding, and not to a discussion of prior processes and their disadvantages.

The last paragraph on page 2, page 3, and the first two paragraphs on page 4, should all be canceled.

The expression "from about two millimeters in thickness downward", introduced by amendment in the description and claims, should be canceled as it involves a departure from the original disclosure.

In the claims the expression "which cannot be welded in the fire of a smithy" should be canceled as it is in the form of a negative limitation; further, it defines no property of the material definitely.

In regard to claim 3, the word "exclusively" involves new matter and is also inaccurate. The subject matter of this claim has not been shown or described.

The claims are all rejected on the patents to Thomson, of record. These patents clearly disclose applicant's process

of welding. As described in patent 444,928, the plates to be welded are pressed together by means of the screw S, thus forming an electrical contact between them, the electric current is then turned on for the purpose of heating the plates and forming a weld between them,- see the description in lines 84 to 94, page 1 of said patent.

Cancel Figures 1 and 2 on the drawing.

R e m a r k s.

In accordance with the requirements of the Official Letter of December 1st 1906 the actual description is confined to applicant's process of welding and all parts of the former description objected to in said Official Letter have been canceled.

In the claim the words "and the like" and the words "Objects" have been changed throughout to -sheets-.

It is thought that the object of the claim is patentable, as the same relates to a series or combination

1.

of single steps not disclosed in the patents to Thomson 496019 and 444928. In the patent to Thomson there is no question of the exerting of a quite intimate pressure at the very point in which the welding joint is to be formed, this being absolutely necessary for example when thin metallic sheets are to be welded together in a series of points consecutively.

Favourable reconsideration and early allowance is requested for.

Very respectfully,

O. E. Duffy & Son

The subject of my invention is a process of welding thin metallic sheets by means of electricity.

As is well known, great difficulties have hitherto been experienced in electrically welding thin metallic sheets and even such a welding was quite generally considered as being impracticable. The thin metallic sheets were still damaged and even burnt through, because sparking could never be avoided. Now, by my improved process I completely overcome the mentioned difficulties.

My process consists in applying suitable electrodes on the metallic sheets at the very point at which the welding joint is to be formed, then causing said electrodes to exert a pressure on the metallic sheets sufficiently to press the metallic sheets intimately together at the point at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and finally maintaining the pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets.

For the purpose of enabling my invention to be

1,100

more readily understood, I will make reference to the accompanying drawing, in which

Fig. 1 is a section of portions of two thin sheets with an air-gap between them.

Fig. 2 is a sectional view illustrating the employment of my new process in welding thin metallic sheets.

Fig. 3 is a like view showing the welding of the overlapping ends of two pieces of sheet metal.

Supposing that thin metallic sheets 5 and 6 (Fig. 1) intended to be welded together by means of electrodes arranged opposite each other loosely lie upon each other or are not subjected to a rational pressure, they still assume at some points air gaps between them, as represented in Fig. 1 in a somewhat exaggerated manner for the sake of easier understanding. If now the electric current is completed through the two electrodes and the sheets, an arc or a line of sparks will be formed as a consequence of the air gap existing between the two thin metallic sheets. However, under the above circumstances, the arc or line of sparks still exerts an injurious action by producing a fusing of the thin metallic sheets to a certain depth or even a complete perforating or burning through of the same.

Now, the essential advantage obtained with my improved process is that in welding thin metallic sheets the formation of an arc or spark, which proves disastrous, is wholly avoided, whereby a perfectly sound welded joint be-

tween two thin metallic sheets, or between a thin metallic sheet and a thicker object, is attained.

For the purpose of preventing the formation of the injurious arc, I submit the superposed thin metallic sheets to be welded (Fig.2 and 3) to a quite intimate pressure at the very point at which the welding joint is to be formed, the amount of said pressure depending upon the nature of the said sheets. This pressure I effect by means of the electrodes a b (Fig. 2 and 3) themselves, or with the aid of other suitable means. The purpose of this intimate pressure is to expel as far as possible the layer of air between the two thin metallic sheets. In this manner the two parts to be welded are, as it were, mechanically connected to form a single homogenous body. This is of great importance when two very thin sheets are to be welded together, for, as is well known, thin sheets have always a more or less wavy form, as far as they have not been straightened in the process of manufacture so as to present a surface which is practically quite flat, such as is the case with thick sheets. Such thin sheets therefore, unless submitted to a heavy mechanical pressure never lie close upon one another; on the contrary, in consequence of the waved form, air gaps are left between them, so that if a current were led through them, it would aid sparking and the formation of arcs.

After the two metal objects have, therefore, been prepared in this way, that is to say, by the application

of a rational mechanical pressure caused to lie quite closely upon each other, without any air-gap between them, the electric circuit is closed, the mechanical pressure being still maintained.

At the place where the electrodes a b exert pressure therefore (Figs. 2 and 3), that is to say, where the current is able to flow through the bodies to be welded without having to pass through a layer of air and form sparks, the metal is heated to welding heat. Immediately this temperature is reached, the continuous pressure effects the desired union, that is to say, welding of the two thin metallic sheets 5 and 6, without injury by perforation or burning, in the manner explained, having taken place, even if the sheets are extremely thin. It should be remarked that the pressure to be exercised on the bodies before and during welding, must be selected according to the thickness of the sheets, and can be adapted to suit the condition of the bodies for the time being. Thicker sheets or objects do not require so much pressure as thin ones because, as already explained, they have a more even, uniform shape and therefore when laid upon each other can be readily closed together, that is to say pressed so that no injurious air gap is formed.

Since the essential condition is, that the two metal objects to be united are firmly pressed together before welding at the very point at which the welding joint is to be formed, it is obvious that with this process not only two equally thin sheets, but a very thin sheet and

a thicker metal object may be welded without danger of the former being burnt through.

Naturally the required superficial pressure may be exerted by only one electrode, or by both the electrodes.

Having thus described my invention, what I claim as new and desire to secure by Letters Patent is :

The process of electrically welding thin metallic sheets, consisting in applying suitable electrodes on the metallic sheets at the very point at which the welding joint is to be formed, then causing said electrodes to exert a pressure on the metallic sheets sufficiently to press the metallic sheets intimately together at the point at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and maintaining the pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets.

J o h a n n H a r m a t t a,

"Electric Welding"

c/o O. E. D u f f y & Son,

Filed Dec. 3, 1903.

Ser. No.183677.

PATENT OFFICE,
DEC 5 1907
DIV. 16, FILED.

Hon. Commissioner of Patents

Sir:

Replying to Official Letter of Dec. 15th, 1906 amendment is made by substituting the following 2 claims to the former one;

Erased
Per G

1.) The process of electrically welding a plurality of metal sheets, consisting in exerting a heavy mechanical pressure by means of electrodes on said sheets, thereby flattening, smoothing out and eliminating all irregularities and intimately pressing said sheets E1 together, whereby air space and interstices between said sheets are eliminated, subsequently passing an electric F current through the sheets thus softening and welding same while maintaining the heavy pressure of the electrodes on the sheets.

2.) The process of electrically welding thin metallic sheets, consisting in applying suitable electrodes on the metallic sheets at the very point at which the welding joint is to be formed, then causing said electrodes to exert a maximum pressure on the metallic

sheets sufficiently to press the metallic sheets intimately together at the point at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and maintaining the maximum pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets.

R e m a r k s .

It is a matter of fact that very great difficulties have formerly been experienced in electrically welding together very thin metallic sheets. Even the welding together of such thin metallic sheets was considered as quite impossible before the applicant obtained a full success in that direction.

The tenor and gist of applicants invention, as clearly stated in the specification forming a part of this specification consists in welding thin sheets of metal such as used in kitchen ware by pressing said sheet together between electrodes with very great or maximum pressure, this pressure being so great that all irregularities and unevenness will be pressed smooth and flattened out of the sheets, and that all air spaces and interstices between the sheets will be eliminated. Then a current is passed in a known manner between the electrodes, whereby the metal is softened and welding takes place, as said very great pressure is maintained.

The new process composed of a certain number of definite steps is clearly specified in the 2 claims filed to-day, and in view of the fact that an effect

1-2017

which before the present application was considered as impossible or inadmissible is obtained, the process forming the object of the present application is thought to be patentable.

Favourable reconsideration of the case is requested for.

Very respectfully,

O. E. Duffy & Son

Ser. No. 183677.

Hon. Commissioner of Patents,

S i r :-

Replying to Official Letter of January 6th, 1908, I beg to state the following :

Kindly have at my costs the drawings altered "P" by the Chief Draughtsman, so that the drawings read 1, 2 and 5;

In claim 1, line 8, substitute through &c for "trough".

As in the Official Letter only the Patent No.496019 to T h o m s o n is referred to it is thought that the former references cited by the Patent Office are now overcome.

Now, the U.S.Patent No.496019 cited in the Official Letter relates only to a soldering method and not to a welding method as in the present application. Therefore the U.S. patent No.496019 according to the belief of applicant cannot be considered as an anticipation of the object of the invention applied for.

The conditions of working and results to be obtained are quite different in both cases and the process of applicant is to be considered as a very useful im-

provement in welding processes in view of the prior state of the art.

On account of the above statements favourable reconsideration and early allowance is requested for.

Respectfully

O. E. Duffy & Son

E. B. Moore,
Commissioner of Patents.

In response to amendment of January 6, 1909.

The term "rational pressure" used in line 12, page 2, and in line 1, page 4, is not understood.

The specification now in the case contains matter for which there is no warrant in the original specification. For example, Fig. 1 and the matter relating thereto involve a departure from the original disclosure. This figure and the matter relating thereto must be canceled, and the specification revised in such a manner as to restrict it to matter illustrated or described in the original disclosure.

Claim 1 is rejected as unwarranted by the original disclosure.

In lines 4 and 7 of claim 2, should not "welding" be changed to welded?

Claim 2 is rejected as presenting nothing patentable over Thomson, 444,928, or 496,016, or Blevins, 758,503, all of record.

It is thought that if there is any patentable matter in this case it resides in the securing of the sheet metal parts together by means of the small round, sharply defined place of welding which answers the purpose of a rivet, as is set forth on page 6 of the original specification.

Hon. Commissioner of Patents,

S i r :-

Replying to Official Letter of February 9th, 1909 amendment is made by substituting the enclosed description, claims and drawing to the former ones.

"G"

R e m a r k s :

The present description, claims and drawing are limited to the subject-matter which in the last Official Letter is deemed patentable by the U. S. Patent Office. Great care has been taken not to describe anything which was not illustrated or explained in the original disclosure.

For the matter which is considered by the U. S. Patent Office as involving a departure from the original disclosure it is intended to file in the next time a divisional application.

It is thought that the two claims submitted at present are allowable. The 1st claim is more specially directed upon the new process or method of uniting the sheet metal parts together. The 2nd claim relates to the

several steps of said process or method.

As applicant strictly complied with the official requirements favourable reconsideration and early allowance is requested for.

V e r y R e s p e c t f u l l y,

O. E. Duffy & Son

R. H. V.

Enclosures:

1 new description
with claims,
1 new drawing.

M./P.

The subject of my invention is a process or method of welding thin metallic sheets at particular places or spots by means of electricity, said process being intended for the manufacture of metal articles of all kinds, specially those of the thinnest sheet metal, such as kitchen-hardware, household vessels or the like, by direct electric welding.

My new process or method of electrically welding thin metallic sheets essentially consists in securing the sheet metal parts together by means of a small round, defined place of welding which perfectly answers the purpose of a rivet.

I preferably carry out my process by means of the following steps consisting in introducing the sheet metal parts to be welded between electrodes having the form of pins, pressing said electrodes firmly together centrally i.e. at the very place at which the welding is to be effected and closing the circuit, whereby the said small round, very sharply defined place of welding is obtained.

For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place of welding by the aid of any of those tech-

nical means which are suitable for producing or transmitting pressure, for example with a press either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power,

In the accompanying drawing.

Fig. 1 is a view illustrating the welding effected according to my new process of two thin metallic sheets of equal thickness, intermittently or at certain spots only.

Fig. 2 is a side elevation of a welding device (also illustrated in part in Fig. 1) according to which the pressure is exercised by pin shaped electrodes, the form of which may be suited to the particular purpose in view, and which may be adapted to work on the smallest possible surface of contact.

Figs. 3 and 4 show two forms which may be adopted for the ends of the contacting electrodes.

In order to effect the welding only at particular places or certain spots, the sheet metal or other bodies, the edges of which lie upon each other, are introduced between the two electrodes a b, as represented in Fig. 1 which as an example shows the welding of two metal sheets. Of the latter the one during the welding operation is pressed firmly upon the other in the direction of the arrow.

For said welding operation the apparatus provided with pin-shaped electrodes a b shown in Fig. 2 may be advantageously employed. The lower electrode b is inserted

-1-

in the conductor c, whilst the upper electrode a is carried by an arm d and by means of a hand-lever e carried by said arm d can be turned on the shaft f in such manner that the points of the electrodes a b approach or recede from each other. If then two superposed sheet metal ends to be welded together are introduced between the electrodes, and the latter then firmly pressed together and the circuit closed, a small round, very sharply defined place of welding is caused which, as already stated above, perfectly answers the purposes of a rivet. In this event, also, especially in the case of thin vessels which are not required to withstand great pressure, the pressure on the place of welding may at the right moment be exactly regulated or kept within the proper limits.

In Figs 3 and 4 the electrodes a^1 b^1 and a^2 b^2 respectively are given special shapes which answer to particular purposes.

Having thus described my invention, what I claim as new and desire to secure by Letters Patent is :-

Erased Per H

1. The process of electrically welding thin metallic sheets, consisting in securing the sheet metal parts together by means of a small round, defined place of welding which answers the purpose of a rivet.

per K Per-H-

1 2. The process of electrically welding thin metallic sheets, which consists in introducing the sheet metal parts to be welded between electrodes having the

Per H

form-of-pins, pressing said electrodes firmly together and closing the circuit, whereby the specified small round, very sharply defined place of welding which answers the purpose of a rivet is obtained, substantially as set forth.

Sir:-

Please amend the above named application asfollows:

H

Cancel claim 1.

Change numeral of claim "2" to 1 and add the following claims:

2: The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

3: The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

4: The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

H[1]

5: Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

6: Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

7: Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

8: Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

H[1] 9: A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaces and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

sert I[1]

10: 13 The process of electrically welding thin metallic sheets consisting in securing together directly overlapping metallic sheets by means of a small defined place of welding which answers the purpose of a rivet.

11: 14 The process of electrically welding thin metallic sheets consisting in overlapping the metal sheet parts to be welded and securing said parts together by means of small defined places of welding only at points.

12: 15 The process of electrically welding thin metallic sheets, which consists in directly overlapping the metallic sheets to be welded, introducing said overlapping metal sheet parts between pin-shaped electrodes, and passing through the electric current, whereby the metal parts at the place of welding become secured at a sharply defined place.

Johann Harmatta. Ser. No. 183,07

In claim 2, lines 3 and 4 cancel "having the form of pins".

REMARKS.

The claims in the patent to Rietzel, #928,701 designated by the Examiner have been inserted into the case as requested.

Please find below a copy of a communication from the Examiner concerning your application for "Electric Welding", filed December 3, 1903, Serial No. 183,677.

Very respectfully,

Room No. 105.

All communications should be addressed to "The Commissioner of Patents, Washington, D. C."

31792

E. B. Moore.

Commissioner of Patents.

Your case, above referred to, is adjudged to interfere with others, hereafter specified, and the question of priority will be determined in conformity with the Rules.

The statement demanded by Rule 110 must be sealed up and filed on or before the 27 *day of* JUN 1910, 190..., *with the subject of the invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is*

INVENTION.

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

3. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

4. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

5. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only

1425

each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

6. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

7. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

8. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

The interference involves your application above identified, and

An application (Patent No. 928,701, Pat'd July 20, 1909) for "Uniting the Component Parts of Composite Sheet Metal Structures", filed by Adolph F. Rietzel, whose post office address is Lynn, Mass., whose attorneys are Townsend & Decker of 141 Broadway, New York City, and whose assignee is the Thomson Electric Welding Company, of Lynn, Mass, a corporation of Maine.

The relation of the counts of the interference to the claims of the respective parties is as follows:

Counts:	Rietzel:	Harmatta:
1	1	2
2	5	3
3	6	4
4	16	5
5	17	6
6	18	7
7	19	8
8	20	9

If the interference is decided against Harmatta all the claims now in the case will be rejected as not patentable over the issue.

E. B. Moore. *Commissioner of Patents.*

The following counts have been added to the above entitled interference:---

9. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

10. The herein described method of uniting two pieces of metal, consisting in passing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

11. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

The preliminary statement required by Rule 110, as to the added counts only, should be filed on or before AUG 14 1911

The relation of the added counts of the interference to the claims of the respective parties is as follows:----

MAILED * * *

Johann Harmatta,

C/o O. E. Duffy and Son,

City.

Please find below a communication from the EXAMINER in charge of your application of,

183,677, filed Dec. 3, 1903)-----

Electric Welding.

E. B. Moore.

Commissioner of Patents.

Applicant having prevailed in his interference with Rietzel (for record see interference file NO. 31,792), this case has been given further consideration.

The subject-matter of the invention as set out in the first paragraph of the present specification, should be amplified in view of the fact that the claims also cover the article produced by the process claimed.

The word "round", on line 10, page 1 and line 9, page 3, is questioned, since it is not thought the place of welding would necessarily be of circular form.

The description of Fig. 1 is thought to be somewhat involved and it is suggested that it be rewritten.

It is also suggested that "suited", line 14, page 2 be replaced by adapted.

In connection with the claims, an additional examination of the art has been made and the following patents are noted as apparently meeting the terms in which certain of the claims are phrased.

Thomson,	375,022,	Dec. 20, 1887,	219 - 10,
Moxham,	496,890,	May 9, 1893,	" "
Perry,	576,069,	Jan. 26, 1897,	(X. Ref) same class,
Payne and Driven	584,120,	Jun. 8, 1897,	same class,
Kleinschmidt,	616,436,	Dec. 20, 1898,	" "
Brown and Morse,	645,066,	Mar. 13, 1900,	" "
Perry,	670,808,	Mar. 26, 1901,	" "

Thomson (this being one patent from a number showing an analogous operation) discloses the welding together at their ends of two bars A and B, by means of an electric current, the bars being pressed together during the welding.

Moxham shows a similar method of welding bars (rails) at their ends.

These two patents appear to anticipate the terms of claim 2, the expression "at spots only", without some qualification, being of sufficient breadth to refer to ends, and pressure and heating current being localized in said spots (ends).

For a similar reason Payne and Driven and Brown and Morse appear to meet the terms of this claim in their disclosure of the welding of two pieces of metal one on the other. It is noted that in these patents carbon electrodes are employed which would negative the idea of much pressure but as in "welding" it is necessary to employ pressure it is considered that pressure must be employed during the operation. These two patents cover and claim the same thing, they having been involved in an interference.

Perry, 576,069 discloses the electric welding of the joints of a wire fence. It would seem that a wire fence could properly be considered as an article of metal and whether the parts welded be joints of wires or small spots in sheets as in claims 2, 3 and 7, would be patentably immaterial. Accordingly,

1435

this patent appears to meet the terms of such claims.

Fig. 6 of Perry, 670,808, appears to meet the terms of claim 2.

The Kleinschmidt patent, showing the joining of splice bars to rails by electric welding at raised portions (spots?) b, appears to be an anticipation of claims 1 to 12 inclusive.

Inasmuch as the claims of this case have previously been considered allowable and those noted above have been contested in an interference with a patent wherein similar claims were granted, a formal rejection is not now made, since upon consideration and explanation it may appear that the references cited have been formally or informally considered in the examining division earlier having jurisdiction of the applications and held not pertinent. It is thought best, however, to note them in order that if the claims do differ from the patents, such differentiation may appear in the record.

Hon. Commissioner of Patents,
Washington, D. C.

U. S. PATENT OFFICE,
OCT 26 1912
DIV. 3.

Sir:

In the matter of the application of Johann Harmatta for Electric Welding filed Dec. 3rd, 1903, Serial No. 183,677;

In reply to the Office letter dated October 17th, 1912, please erase all previous specifications, claims and amendments thereto and substitute the following:

K1

My invention relates to the manufacture of metal articles of all kinds and consists in a novel method of fastening the component parts together by the process of electric welding and also in the new article produced thereby.

The invention affords a cheap and practical substitute for riveting and is particularly useful in fastening plates or sheets of metal to one another inasmuch as it may be employed for the thinner sheet metal, such for instance as is used for sheet metal ware like vessels or household utensils.

In general terms the invention may be stated to consist in fastening the pieces together by an electric weld at one or more distinct or well-defined spots, each of small area or extent, in their juxtaposed or opposite plane faces by the application of pressure and heating current localized in such spots, and in the special method of localizing the heating and the pressure in the spot or

spots as hereinafter described and specified more particularly in the claims.

It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces. It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces.

A weld formed according to my invention is distinguished however from such prior welds, among other things, by the fact that the opposed surfaces available for uniting the pieces together and in which it might be possible to form a weld are welded in a small spot or spots only, the spot or spots being surroudned by comparatively large areas of opposed surfaces in which no weld is made.

By the term "electric welding" as used herein I mean that wellknown process in which the work is brought to the welding temperature by internal heat generated by the resistance of the work itself to the passage of an electric current at the place of contact between the parts to be joined by the welding pressure, and I disclaim those processes of fastening pieces of metal together in which the parts are heated and practically melted down by an

electric arc generated on the back of the piece by "drawing" an arc by means of the electrode, as well as other processes in which the welding heat is generated externally and electrically in a resistance material and is imparted to the work by heat conduction from said resistance material in contact with the work.

While it is possible, consistently with my invention, to localize the desired pressure and heating current at the desired distinct small spot or area in various ways, this may be accomplished conveniently by pressure applied over the spot and itself localized on the back of the plate or sheet immediately over the small spot in which the union is to be made by using a tool pressed against the work by its end and formed at such end so as to engage the work by a spot or area of small extent and serving, likewise, by preference, as the electrode which feeds the current into the work to heat the same. The member which feeds the electricity being thus at the same time the tool, in this manner the most favorable conditions of working possible are secured, since, as is wellknown, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough.

For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place of welding by the aid of any of those technical means which are suitable for producing or transmitting pressure, e.g., with

a press either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power, or by other means.

In the accompanying drawings, Fig. 1 illustrates the application of my invention to the welding of two plates or sheets overlapped so as to be superposed or have a portion only of their meeting faces presented to one another and by the welding of the opposed surfaces intermittently or at certain spots only through applying pressure at a point or spot on the back of a plate over the spot of desired union.

Fig. 2 is a side elevation of a welding device, also illustrated in part in Fig.1. It shows the construction of the means which may be employed for pressing the electrode against the work by manual power.

Figs. 3 and 4 show forms which may be adopted for the ends of the electrodes where they engage the work.

Electrodes a, b are by preference both formed to engage the work by a small area of contact and may each be adapted to work on the smallest possible surface contact, so as to localize the pressure and the path of the heating current in a very small spot only. The lower electrode b may be inserted in a conductor c and forms one pole of the heating current, while the upper electrode is carried by an arm d, which can be turned on a shaft

f by means of a hand lever e, and is connected with the opposite pole of the circuit feeding current to the work. By this means the electrode a may be caused to approach and recede from the electrode b and to exert pressure upon the back of the two superposed sheet-metal pieces introduced between the electrodes for the purpose of welding. The two superposed metal plates to be welded together being in position between the electrodes as indicated in Fig. 1, the operation is performed by firmly pressing the electrode a down upon the work with any required degree of pressure by means of the lever e and the circuit is closed by any suitable means, thus producing a flow of heating current through the work itself substantially localized therein so as to bring the same to the necessary welding temperature at the desired spot only, and the application of pressure by the use of the lever e will result in the welding of the plates together in the small sharply defined place of welding at the point or spot desired, which perfectly answers the purpose of a rivet. In this event, especially in the case of thin vessels which are not required to withstand great pressure, the pressure on the place of welding may at the right moment be exactly regulated or kept within the proper limits. Obviously, the operation may be repeated upon thework at another point if it is desired to join the pieces at a number of spots only.

The time or duration of pressure and heating and the amount of pressure as well as the volume of current for effecting the weld can be

readily determined by experiment for different sizes or thicknesses of metal and as well understood in the art of electric welding to which my invention relates.

The operation is completed with the cutting off of the flow of current in the usual manner practiced in the art of electric welding and the withdrawal of pressure when desired to permit the work to be withdrawn from position between the electrodes.

Sheet metal work made by this process is readily distinguished from that made by prior processes by the comparative absence of burning, roughening or disintegration of the material on the back of the plate when the operation is carefully conducted. It further possesses the advantage that there are no rivet heads to mar the finish of the back or outer surfaces of the plate.

I am aware that it has been before proposed to fasten two sheets of metal together by electrically welding them over practically the whole area of their opposed or lapping surfaces.

I am also aware of patent to H. F. A. Kleinschmidt No. 616,436, dated December 20th, 1898, and do not wish to be understood as claiming anything disclosed in said patent.

What I claim as my invention is:-

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to

produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

7. The process of electrically welding thin metallic sheets, which consists in introducing the sheet metal parts to be welded between electrodes, pressing said electrodes firmly together and closing the circuit, whereby a small, sharply defined place of welding which answers the purpose of a rivet is obtained, substantially as set forth.

8. The method of electrically welding two plates or sheets of metal together face to face between electrodes, consisting in restricting the area of contact of an electrode with said plates

to a spot, passing a heating electric current from said electrode to the co-operating electrode through said spot to heat the work to welding temperature and applying pressure to the work in line with said spot to effect a welding of one plate to the other.

9. The herein described method of producing a welding temperature in a small distinct spot or point of the opposed surfaces of two plates of metal, consisting in applying pressure at a point or spot only at the back of a plate coinciding with the desired point or spot of welding, while the plates are assembled face to face, to localize the flow of current in the required point or spot in the meeting surfaces and passing an electric current through the plates in the line of the applied pressure to bring the material to welding temperature at the spot of welding by the resistance of the work to the passage of such current.

10. The method of electrically welding a piece of sheet metal at a small distinct spot or point in its plane surface to the face of another piece of metal, consisting in applying pressure at a small point or spot on the back of the sheet to localize the pressure and electrical heating of the work at a spot of electrical contact in the opposed surfaces of said pieces beneath the point of applied pressure, and passing an electric current from one to the other at the said spot of localized electrical contact to produce a welding temperature at said spot and maintaining the localized pressure to effect a welding at said spot.

11. The herein described method of welding two pieces of sheet metal together by a weld at a small spot only of their opposed surfaces, consisting in applying pressure localized in a spot on the back of a sheet directly over the desired spot of union, while said sheet is assembled face to face with the opposite sheet and so as to localize the pressure and electrical heating in a spot in the meeting surfaces of the sheets, and effecting the weld by passing an electrical current from one sheet to the other through said spot in the line of the localized applied pressure, and by pressure applied in said line.

12. The method of electrically welding two pieces of sheet metal to one another, consisting in pressing the sheets together by pressure applied and localized in a distinct well-defined point or spot on the rear surface of asheet while passing an electric current through them in the line of the pressure, thereby localizing the path of the heating current from one to the other of the meeting surfaces of the sheets to cause the said sheets to be heated to welding temperature by the electric resistance of the work at said spot, and applying pressure localized over said spot whereby the pieces are welded together at a distinct well defined spot in their meeting surfaces answering the purpose of a rivet.

13. The method of electrically welding two plates of metal together face to face, consisting in pressing the plates together between two elec-

trodes one of which at least makes contact with the rear of a plate at a spot only, feeding a heating electric current into the plates by said electrodes to bring the plates to welding temperature by the heating effect due to the electrical resistance of the portion of the circuit containing said plates, and effecting an electric welding of one plate to the other at a spot beneath the electrode by the pressure of said electrode.

14. The herein described method of fastening two sheets of metal together at a distinct point or spot only in their plane meeting surfaces, consisting in pressing the sheets together and localizing the contact pressure of each upon the other at the said distinct spot or point, passing an electric current from one sheet to the other through said localized spot of contact pressure between them to bring the metal to welding temperature in said spot and thereupon completing the weld in the material so brought to welding temperature and uniting the pieces by a welded union at said spot only.

15. The herein described method of fastening two pieces or sheets of metal together at a spot only in their meeting surfaces, consisting in pressing them together at said spot, passing an electric current through said pieces or sheets at said spot to raise the same to welding temperature and applying welding pressure localized in the back of a sheet immediately over said spot to effect the weld.

16. The herein described method of welding two pieces of sheet metal together by pressing them to-

gether between electrodes engaging the surface of the sheets at a spot only and bringing the section of work between them to the welding temperature by its resistance to the passage of an electric current fed through the work by said electrodes.

17. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

18. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

19. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

20. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot

being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

21. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

REMARKS:

In reply to the official action dated October 17th, the applicant submits the above substitute specification and claims.

Some of the patents now cited by the Examiner were specifically cited in the Rietzel case against the allowance of many of the claims now submitted by applicant and the considerations made of record in the Rietzel application were evidently recognized by the Examiners having charge of that case as rendering those patents inapplicable. As to other patents which the present Examiner now cites for the first time, the same considerations apply forcibly. They were doubtless influential with the Examiner who acted on the Rietzel case and for this reason he did not cite these additional patents whose existence must have been known to him.

The specification as now drawn with its differentiating clauses clearly differentiates the invention from the references. However, we call

the attention of the Examiner to the facts submitted here below which, among many others that might be referred to, establish clearly that this applicant has made a definite advance in this art for which he is entitled to the protection of a patent.

The resemblance between the processes of welding disclosed in the Thomson and Moxham patents and that of applicant is, to say the least, extremely remote. In both those cases the patentees contemplate the formation of a weld not limited to a spot in the opposed or meeting surfaces but the formation of a welded union over substantially the whole area of the metal pieces taken in cross-section and on a line immediately back of the welded union. Welding according to those patents, is, in its essentials, a welding of the whole opposed areas or surfaces. Other patentees, in their attempt to weld plates of metal, followed out the suggestions of the Thomson patent and others in which an end welding of pieces is described, by attempting to weld practically the whole of the plane surfaces of the plates together. In neither case is there anything in the nature of a welding of juxtaposed or opposite faces of the pieces or plates at a "spot" in the ordinary acceptation of the term "spot" and as defined by the dictionary, nor in the sense of the term "spot" as defined in Harmatta's substitute specification submitted herewith. It seems to applicant that the term "spot" has no application whatever to the weld produced by the welding of two bars or pieces of metal end to end over substantially their whole cross-sectional area.

Regarding the Payne and Diven patent, it is quite clear that the patentees contemplated only the union of the plates by a lapped joint involving practically the whole area of the lapping surfaces. There is not a word in the patent about so limiting the area of heating of the metal that the welding temperature will be reached in only a spot in the opposed surfaces.

In the Brown & Morse patent there is likewise an entire absence of any disclosure indicating that the patentees contemplated anything but a union of the strips over practically their whole meeting or opposed surfaces. All the statements made in the specification are consistent with the idea that a union over the whole surface of the plate was the thing in view, as for instance, where the patentees speak of the welding of flat copper bonding strips directly to the rails of electric railways, in which case it is quite obvious that the union should be over the whole surface in order to afford the desired conductivity at the point of junction of the bond and rail.

Furthermore, the Brown & Morse as well as the Payne & Diven process is one in which the metal is brought to the welding temperature by an external source of heat conducted into the metal pieces from the back and which would necessarily diffuse itself over substantially the whole areas of the opposed pieces and so that the localization of the heating to a welding temperature in a spot in the opposed surfaces would be practically impossible.

Furthermore, it is apparent that a welding at a spot in the ordinary sense of the term "welding" as employed in this art is not practical with carbon electrodes, since the electrode, if shaped to exert pressure at a spot, would be extremely liable to break because of its fragile nature.

In short, the Brown & Morse method is not a true electric welding process in the sense of the term "electric welding" as ordinarily used in the art and as defined by this applicant in the body of the substitute specification herewith submitted.

In respect to the Perry fence patent, we can find nothing but a union of the elements of the structure over substantially the whole of the meeting surfaces. To say that there is a welding at spots only, seems to the applicant to employ the term out of its ordinary significance and to imply that the void spaces between the metal portions are to be considered as a part of the opposed surfaces to be welded, which obviously they are not.

The patent to Perry 670,808 presents a method that only apparently resembles applicant's invention and in substance is essentially different therefrom. There is no localization of the welding in a spot only of the opposed surfaces in which a welding might take place. So far as the balls are concerned, the welding contact is at the mathematical point at which the surfaces of two spheres may, geometrically considered, make contact with one another. It would be physically impossible to weld the balls at any other than such point of contact and parts immediately contiguous thereto, so that while in one sense and from a purely geometrical standpoint,

there is a spot at which the surfaces may touch, nevertheless in the practical sense of the welding of two pieces systematically limited to a spot only in their weldable opposed or meeting surfaces, the idea of applicant and the essence of his invention are totally absent. The same consideration applies with equal force to the mere welding of two crossing wires together at an intersection, provided it be possible to consider such welding, as disclosed in the Perry patent and practiced in actual fence welding, to be a welding in a spot in any sense rather than a substantial welding of all of the meeting sides of the wires where their sides lie against one another.

The Kleinschmidt patent does not disclose the idea of welding at a spot only in the ordinary sense of the term "spot". The Standard Dictionary defines "spot" thus:

1. A particular place of small extent; a definite locality; as, the spot where Columbus first landed.
2. Any small portion of a surface differing in color from the rest.
3. A minute piece or bit; particle; atom.

The patentee Kleinschmidt was dealing with large masses of metal and with a construction in which provision had been made to withstand extreme shearing strain.

For the purposes of the use of the finished production a weld across the whole face of the plate would be desirable, and this the patentee specifically aims at in the union at the place B Fig. 2. For other and specific purposes he modifies the shape of the projection b without idea or purpose of confining the extent of the weld to a "spot". It may be noted

that the cross-sectional view, Fig. 3, shows a welding across the whole face of the plate but independently of this suggestion or any inference to be drawn therefrom it is quite clear that if the weld were or could be confined to the areas represented by the projection b, said projections are so large that there would not be a welding in a "spot" in the usual sense of the term and consistently with what applicant has set out as his invention. To avoid any question, however, as to whether this patent should constitute a bar to the allowance in this case the applicant has specifically disclaimed the said patent by specific reference thereto in the body of his specification.

The above arguments are in conformity with those advanced at great length before the Principal Examiner, Mr. Rich, during numerous interviews had by one of the attorneys in this case, and it has been agreed by Mr. Rich, as the result of such interviews, that the above amendment places this case in condition for allowance.

Respectfully submitted,

JOHANN HARMATTA,

By

O. E. Duffy & Son

ADDRESS ONLY THE COMMISSIONER OF PATENTS WASHINGTON, D. C.

K.O'D. 2-181 Serial No. 183,677.

DEPARTMENT OF THE INTERIOR

UNITED STATES PATENT OFFICE

WASHINGTON Oct. 31, 1912.

Johann Harmatta, Assor.

Sir: Your APPLICATION for a patent for an IMPROVEMENT in

Electric Welding,

filed Dec. 3, 1903, has been examined and ALLOWED.

The final fee, TWENTY DOLLARS, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent on this application will be withheld, unless renewed with an additional fee of $15, under the provisions of Section 4897, Revised Statutes.

The office delivers patents upon the day of their date, and on which their term begins to run. The printing, photolithographing, and engrossing of the several patent parts, preparatory to final signing and sealing, will require about four weeks, and such work will not be undertaken until after payment of the necessary fee.

When you send the final fee you will also send, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR and TITLE OF INVENTION AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If you desire to have the patent issue to ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of final fee.

After issue of the patent uncertified copies of the drawings and specifications may be purchased at the price of FIVE CENTS EACH. The money should accompany the order. Postage stamps will not be received.

Final fees will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

Respectfully,

E. B. Moore.

Commissioner of Patents.

O. E. Duffy & Son,

Wash. D. C.

IN REMITTING THE FINAL FEE GIVE THE SERIAL NUMBER AT THE HEAD OF THIS NOTICE.

UNCERTIFIED CHECKS WILL NOT BE ACCEPTED.

$20.00 RECEIVED
NOV 5 1912 H.
CHIEF CLERK U.S.PATENT OFFICE

Washington, D.C.

Please find below a copy of a communication from the Examiner concerning the patent of Johann Harmatta, for Electric Welding, # 1046066, dated Dec. 3, 1912, (serial number 183,677 filed Dec. 3, 1903).

Paper No. 175

ADDRESS ONLY THE COMMISSIONER OF PATENTS WASHINGTON, D. C.

Very respectfully.

Thomas Ewing

Commissioner of Patents.

36709

The case, above referred to, is adjudged to interfere with others, hereafter specified, and the question of priority will be determined in conformity with the Rules.

The statement demanded by Rule 110 must be sealed up and filed on or before DEC 1 1913 *, with the subject of the invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is*

1. The hereinbefore described improved mathod of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

The interference involves your patent above identified, and an application for Electric Welding, filed by Sebastian Ziani de Ferranti, whose post office address is Grindleford Bridge, Sheffield, England, and whose attorneys are Spear, Middleton, Donaldson and Spear, Washington, D. C.

The relation of the counts of the interference to the claims of the respective parties is as follows:--

UNITED STATES PATENT OFFICE.

JOHANN HARMATTA, OF SZEPESVÁRALJA, AUSTRIA-HUNGARY, ASSIGNOR TO THOMSON ELECTRIC WELDING COMPANY, OF LYNN, MASSACHUSETTS, A CORPORATION OF MASSACHUSETTS.

ELECTRIC WELDING.

1,046,066. Specification of Letters Patent. Patented Dec. 3, 1912.

Application filed December 3, 1903. Serial No. 185,677.

To all whom it may concern:

Be it known that I, JOHANN HARMATTA, engineer, a subject of the King of Hungary, residing at Szepesváralja, in the Empire of Austria-Hungary, have invented new and useful Improvements in Electric Welding, of which the following is a specification.

My invention relates to the manufacture of metal articles of all kinds and consists in a novel method of fastening the component parts together by the process of electric welding and also in the new article produced thereby.

The invention affords a cheap and practical substitute for riveting and is particularly useful in fastening plates or sheets of metal to one another inasmuch as it may be employed for the thinner sheet metal, such for instance as is used for sheet metal ware like vessels or household utensils.

In general terms the invention may be stated to consist in fastening the pieces together by an electric weld at one or more distinct or well-defined spots, each of small area or extent, in their juxtaposed or opposite plane faces by the application of pressure and heating current localized in such spots, and in the special method of localizing the heating and the pressure in the spot or spots as hereinafter described and specified more particularly in the claims.

It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces. It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces.

A weld formed according to my invention is distinguished however from such prior welds, among other things, by the fact that the opposed surfaces available for uniting the pieces together and in which it might be possible to form a weld are welded in a small spot or spots only, the spot or spots being surrounded by comparatively large areas of opposed surfaces in which no weld is made.

By the term "electric welding" as used herein I mean that wellknown process in which the work is brought to the welding temperature by internal heat generated by the resistance of the work itself to the passage of an electric current at the place of contact between the parts to be joined by the welding pressure, and I disclaim those processes of fastening pieces of metal together in which the parts are heated and practically melted down by an electric arc generated on the back of the piece by "drawing" an arc by means of the electrode, as well as other processes in which the welding heat is generated externally and electrically in a resistance material and is imparted to the work by heat conduction from said resistance material in contact with the work.

While it is possible, consistently with my invention, to localize the desired pressure and heating current at the desired distinct small spot or area in various ways, this may be accomplished conveniently by pressure applied over the spot and itself localized on the back of the plate or sheet immediately over the small spot in which the union is to be made by using a tool pressed against the work by its end and formed at such end so as to engage the work by a spot or area of small extent and serving, likewise, by preference, as the electrode which feeds the current into the work to heat the same. The member which feeds the electricity being thus at the same time the tool, in this manner the most favorable conditions of working possible are secured, since, as is well known, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough.

For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place of welding by the aid of any of those technical means which are suitable for produc

ing or transmitting pressure, *e. g.*, with a press either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power, or by other means.

In the accompanying drawings, Figure 1 illustrates the application of my invention to the welding of two plates or sheets overlapped so as to be superposed or have a portion only of their meeting faces presented to one another and by the welding of the opposed surfaces intermittently or at certain spots only through applying pressure at a point or spot on the back of a plate over the spot of desired union. Fig. 2 is a side elevation of a welding device, also illustrated in part in Fig. 1. It shows the construction of the means which may be employed for pressing the elctrode against the work by manual power. Figs. 3 and 4 show forms which may be adopted for the ends of the electrodes where they engage the work.

Electrodes *a*, *b* are by preference both formed to engage the work by a small area of contact and may each be adapted to work on the smallest possible surface contact, so as to localize the pressure and the path of the heating current in a very small spot only. The lower electrode *b* may be inserted in a conductor *c* and forms one pole of the heating current, while the upper electrode is carried by an arm *d*, which can be turned on a shaft *f* by means of a hand lever *e*, and is connected with the opposite pole of the circuit feeding current to the work. By this means the electrode *a* may be caused to approach and recede from the electrode *b* and to exert pressure upon the back of the two superposed sheet-metal pieces introduced between the electrodes for the purpose of welding. The two superposed metal plates to be welded together being in position between the electrodes as indicated in Fig. 1, the operation is performed by firmly pressing the electrode *a* down upon the work with any required degree of pressure by means of the lever *e* and the circuit is closed by any suitable means, thus producing a flow of heating current through the work itself substantially localized therein so as to bring the same to the necessary welding temperature at the desired spot only, and the application of pressure by the use of the lever *e* will result in the welding of the plates together in the small sharply defined place of welding at the point or spot desired, which perfectly answers the purpose of a rivet. In this event, especially in the case of thin vessels which are not required to withstand great pressure, the pressure on the place of welding may at the right moment be exactly regulated or kept within the proper limits. Obviously, the operation may be repeated upon the work at another point if it is desired to join the pieces at a number of spots only.

The time or duration of pressure and heating and the amount of pressure as well as the volume of current for effecting the weld can be readily determined by experiment for different sizes or thicknesses of metal and as well understood in the art of electric welding to which my invention relates.

The operation is completed with the cutting off of the flow of current in the usual manner practiced in the art of electric welding and the withdrawal of pressure when desired to permit the work to be withdrawn from position between the electrodes.

Sheet metal work made by this process is readily distinguished from that made by prior processes by the comparative absence of burning, roughening or disintegration of the material on the back of the plate when the operation is carefully conducted. It further possesses the advantage that there are no rivet heads to mar the finish of the back or outer surfaces of the plate.

I am aware that it has been before proposed to fasten two sheets of metal together by electrically welding them over practically the whole area of their opposed or lapping surfaces. I am also aware of patent to H. F. A. Kleinschmidt No. 616,436, dated December 20th, 1898, and do not wish to be understood as claiming anything disclosed in said patent.

What I claim as my invention is:—

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and

passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

7. The process of electrically welding thin metallic sheets, which consists in introducing the sheet metal parts to be welded between electrodes, pressing said electrodes firmly together and closing the circuit, whereby a small, sharply defined place of welding which answers the purpose of a rivet is obtained, substantially as set forth.

8. The method of electrically welding two plates or sheets of metal together face to face between electrodes, consisting in restricting the area of contact of an electrode with said plates to a spot, passing a heating electric current from said electrode to the coöperating electrode through said spot to heat the work to welding temperature and applying pressure to the work in line with said spot to effect a welding of one plate to the other.

9. The herein described method of producing a welding temperature in a small distinct spot or point of the opposed surfaces of two plates of metal, consisting in applying pressure at a point or spot only at the back of a plate coinciding with the desired point or spot of welding, while the plates are assembled face to face, to localize the flow of current in the required point or spot in the meeting surfaces and passing an electric current through the plates in the line of the applied pressure to bring the material to welding temperature at the spot of welding by the resistance of the work to the passage of such current.

10. The method of electrically welding a piece of sheet metal at a small distinct spot or point in its plane surface to the face of another piece of metal, consisting in applying pressure at a small point or spot on the back of the sheet to localize the pressure and electrical heating of the work at a spot of electrical contact in the opposed surfaces of said pieces beneath the point of applied pressure, and passing an electric current from one to the other at the said spot of localized electrical contact to produce a welding temperature at said spot and maintaining the localized pressure to effect a welding at said spot.

11. The herein described method of welding two pieces of sheet metal together by a weld at a small spot only of their opposed surfaces, consisting in applying pressure localized in a spot on the back of a sheet directly over the desired spot of union, while said sheet is assembled face to face with the opposite sheet and so as to localize the pressure and electrical heating in a spot in the meeting surfaces of the sheets, and effecting the weld by passing an electrical current from one sheet to the other through said spot in the line of the localized applied pressure, and by pressure applied in said line.

12. The method of electrically welding two pieces of sheet metal to one another, consisting in pressing the sheets together by pressure applied and localized in a distinct well-defined point or spot on the rear surface of a sheet while passing an electric current through them in the line of the pressure, thereby localizing the path of the heating current from one to the other of the meeting surfaces of the sheets to cause the said sheets to be heated to welding temperature by the electric resistance of the work at said spot, and applying pressure localized over said spot whereby the pieces are welded together at a distinct well defined spot in their meeting surfaces answering the purpose of a rivet.

13. The method of electrically welding two plates of metal together face to face, consisting in pressing the plates together between two electrodes one of which at least makes contact with the rear of a plate at a spot only, feeding a heating electric current into the plates by said electrodes to bring the plates to welding temperature by the heating effect due to the electrical resistance of the portion of the circuit containing said plates, and effecting an electric welding of one plate to the other at a spot beneath the electrode by the pressure of said electrode.

14. The herein described method of fastening two sheets of metal together at a distinct point or spot only in their plane meeting surfaces, consisting in pressing the sheets together and localizing the contact pressure of each upon the other at the said distinct spot or point, passing an electric current from one sheet to the other through said localized spot of contact pressure between them to bring the metal to welding

temperature in said spot and thereupon completing the weld in the material so brought to welding temperature and uniting the pieces by a welded union at said spot only.

15. The herein described method of fastening two pieces or sheets of metal together at a spot only in their meeting surfaces, consisting in pressing them together at said spot, passing an electric current through said pieces or sheets at said spot to raise the same to welding temperature and applying welding pressure localized in the back of a sheet immediately over said spot to effect the weld.

16. The herein described method of welding two pieces of sheet metal together by pressing them together between electrodes engaging the surface of the sheets at a spot only and bringing the section of work between them to the welding temperature by its resistance to the passage of an electric current fed through the work by said electrodes.

17. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

18. Sheet metal work comprising pieces of sheet meal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

19. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

20. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

21. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

In witness whereof I have hereunto signed my name this 5th day of November, 1903, in the presence of two subscribing witnesses.

JOHANN HARMATTA.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE,

WASHINGTON, D. C.,

Oct. 2, 1913.

Examiner of Interferences:

An interference is found to exist between the following cases, and in respect to the invention therein specified, to wit:

CASES.

1. Name, Sebastian Ziani de Ferranti; Post-office address, Grindleford Bridge, Sheffield, England; Title, Electric Welding; Filed Dec. 29, 1911, Ser. No. 668,464 (Division of application No. 208,034, May 14, 1904); Attorney, Spear, Middleton, Donaldson and Spear, Washington, D. C.
2. Name, Johann Harmatta; Post-office address, Szepesvaralja, Austria-Hungary; Title, Electric Welding; Filed Dec. 3, 1903, Ser. No. 183,677; Patented Dec. 3, 1912, No. 1,046,066; Attorney, O. E. Duffy and Sons, of 612 F St., N. W., Washington, D. C.; Assignee, Thomson Electric Welding Company, Lynn, Massachusetts.

Intf. Number 36,709.
Intf. declared Oct. 7, 1913.
Statements due Dec. 1, 1913.

INVENTION.

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current

through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

The relation of the counts of the interference to the claims of the respective parties is as follows:

IN RE INTERFERENCE No. 36,709.

JOHANN HARMATTA

vs.

SEBASTIAN ZIANI DE FERRANTI.

PRELIMINARY STATEMENT OF JOHANN HARMATTA.

JOHANN HARMATTA, a subject of the King of Hungary, residing at Szepesvaralja, in the Kingdom of Hungary, being duly affirmed, deposes and says that he is a party to the interference declared by the Commissioner of Patents on the 7th day of October 1913, between his patent No. 1,046,066, dated December 3d 1912, and an application for a similar invention filed by Sebastian Ziani de Ferranti; that he conceived the invention set forth in the declaration of interference at the end of the year 1900, without having had then the opportunity of carrying out said invention for lack of time; that on or about the 15th day of September 1901, as he set working his own manufactory at Szepesvaralja, he first made drawings of the device for carrying out the process set forth in the claims involved in the interference; that in the first days of October 1901 he modified an old chain-welding machine so as to be able to carry out said process as set forth in the claims involved in the interference; that on the 15th of to the 20th day of October 1901, he had thin iron sheets welded and attachments welded upon sheet metal vessels successfully and on a manufacturing scale by his workmen, Michael Hozza and Michael Tomaskiewicz, with the help of the process forming the object of the claims involved in the interference; said two workmen, which live here at Szepesvaralja and which remember very well to have performed the said work at the mentioned time, being ready to give testimony in respect of the above facts; that in the course of November 1901 he mentioned said electric weldings of thin iron sheets to Mr. Hegenscheidt, Director General of the firm "Oberschlesische Eisenindustrie A. G." (Upper Silesian Iron Industry Company of share-holders) at Gleiwitz, Silesia, Germany, in the presence of the Chief Engineer of said Mr. Hegenscheidt, Mr. Wilhelm Fischer, which is at present Director, and that said gentlemen promised to inform the firm

"Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz, Silesia, Germany, about the said electric weldings of thin iron sheets; that the firm "Eisenhütte Silesia" received said information from said gentlemen, but raised doubts about the possibility of electrically welding such thin iron sheets without danger of burning through said metal sheets; that said firm "Eisenhütte Silesia," for the sake of verification, sent during the summer of the year 1902, to him (Harmatta) several blanks of sheet metal utensils, which he (Harmatta) welded, with the help of the process forming the object of the claims involved in the interference, to the thorough satisfaction of said "Eisenhütte Silesia"; that then Mr. Schweisfurth of Paruschowitz, technical Director of the firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz, Silesia, Germany came to him in order to look at the electric weldings and the modified chain-welding machine; and, as said Mr. Schweisfurth had convinced himself by ocular proof that it is very easy to weld such thin iron sheets with the help of the process forming the object of the claims involved in the interference, the said firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz acquired the property of said process by a contract made with him (Harmatta) at the date of February 12th 1902, and that from the month of January 1903 a great number of full-size machines adapted to carry out the welding process forming the object of the claims involved in the interference have been manufactured by said "Eisenhütte Silesia" for personal use and sale to others; the first new and full-size machine of this kind having been completed in the last days of January 1903 and first successfully operated and used in February 1903 for carrying out his process, in the works of the "Eisenhütte Silesia," in the village of Paruschowitz, Silesia (Germany).

That patents for such invention were applied for and obtained as follows:

Application filed in Germany, March 24th 1903, published June 20th 1904, patent not granted;

Application filed in Sweden, October 12th 1903, patent dated October 12th 1903, No. 24,035; published the 16th day of November 1907 and granted the 23rd day of January 1908;

Application filed in France, October 13th 1903, patent dated October 13th 1903, No. 336,187; published the 1st day of March 1904 and granted the 7th day of January 1904;

Application filed in Austria, October 14th 1903, patent dated August 1st 1905, No. 24,335; published the 8th day of January 1905 and granted the 30th day of March 1906;

Application filed in Denmark, October 14th 1903; published May 16th 1905, patent not granted;

Application filed in Luxemburg, October 14th 1903, patent dated October 15th 1903, No. 5300; published the 14th day of October 1903 and granted the 14th day of October 1903;

Application filed in Hungary, October 15th 1903, patent dated

October 15th 1903, No. 31,382; published the 29th day of April 1904 and granted the 24th day of August 1904;

Application filed in Switzerland, October 15th 1903, patent dated October 15th 1903, No. 29,723; published June 21st 1905 and granted the 21st day of June 1905;

Application filed in Belgium, October 16th 1903, patent dated October 16th 1903, No. 173,119; published the 20th day of January 1904 and granted the 31st day of October 1903;

Application filed in Russia, October 20th 1903, patent not granted.

Application filed in Spain, October 20th 1903, patent dated October 10th 1903, No. 32,726; published the 10th day of December 1903 and granted the 10th day of December 1903;

Application filed in Italy, October 22nd 1903, patent dated October 22nd 1903, No. 180/117; published the 16th day of December 1903 and granted the 16th day of December 1903;

Application filed in Great Britain, October 23rd 1903, patent dated October 23rd 1903, No. 22981/1903; published the 20th day of October 1904 and granted the 25th day of August 1904;

Application filed in Canada, December 4th 1903, patent not granted;

Application filed in Japan, December 14th 1903, patent dated April 6th 1905, No. 8640; published the 6th day of April 1905 and granted the 6th day of April 1905;

Application filed in Romania, July 11th 1906, patent not granted.

That such invention was fully described in the following patent specifications:

Sweden No. 24,035;
France No. 336,187;
Austria No. 24,335;
Hungary No. 31,382;
Switzerland No. 29,723;
Great Britain No. 22981/1903;
Japan No. 8640.

The knowledge of such invention was first introduced in the United States on or about December 3rd 1903 by the papers belonging to United States application for patent Serial Number 183,677, filed December 3rd 1903, the said papers being the application upon which the aforesaid patent No. 1,046,066 was granted, said application papers having been sent by deponent to Messrs. Marion & Marion at Montreal, Canada, who filed said application in the United States Patent Office on or about December 3rd 1903.

Nov. 26, 1913.

Before the Examiner of Interferences:

Intf. No. 36709.

In the matter of the interference of Harmatta vs. de Ferranti.

SIR:

You are hereby informed that the preliminary statement of Harmatta has been received and filed.

By direction of the Commissioner:

Very respectfully,

W. F. WOOLARD,
Chief Clerk.

O. E. Duffy & Sons,
612 F St. N. W.
6—2051 Washington, D. C.

(Printed Letter Head Omitted)

Washington, D. C., November 25, 1913.

Hon. Commissioner of Patents,
Washington, D. C.

SIR:

We enclose herewith preliminary statement of Sebastian Z. de Ferranti, in the interference of de Ferranti vs. Harmatta, No. 36709. We call attention to the early date of filing of the British patent of de Ferranti, under which a convention date is claimed of May 25, 1903, and as the date of filing of the Harmatta case is later than this it is asked that de Ferranti be regarded as the senior party in the interference in the setting of times for taking testimony.

Respectfully,
SPEAR, MIDDLETON, DONALDSON & SPEAR.
By ELLIS SPEAR.

INTERFERENCE No. 36709.

In the matter of the interference between

SEBASTIAN ZIANI DE FERRANTI

AND

THE THOMSON ELECTRIC WELDING COMPANY,

Assignees of JOHANN HARMATTA.

PRELIMINARY STATEMENT OF SEBASTIAN ZIANI DE FERRANTI.

Kingdom of Great Britain and Ireland, City of London, England, ss:

SEBASTIAN ZIANI DE FERRANTI, Engineer, of Baslow, in the County of Derby, England (late of Grindleford Bridge, Sheffield, in the County of Derby, England, and of 31, Lyndhurst Road, Hampstead, London, England,) being duly sworn, doth depose and say:

THAT he is a party to the above numbered Interference declared by the Commissioner of Patents, dated October 7th, 1913, between his application Serial No. 668461, filed December 29th, 1911, "ELECTRIC WELDING", which was itself divided off from his Patent Application Serial No. 208034, filed May 14th, 1904, for a "PROCESS AND APPARATUS FOR ELECTRICALLY WELDING TURBINE BLADES TO THEIR CARRYING ELEMENTS", and Patent No. 1,046,066, granted to THE THOMSON ELECTRIC WELDING COMPANY, Lynn, Massachusetts, Assignees of JOHANN HARMATTA, of Szepesvaralja, Austria-Hungary, for "ELECTRIC WELDING", the application in pursuance of which said patent was granted having been filed by him on 3rd December 1903, bearing the Serial No. 183677.

THAT he conceived and made the invention set forth in the Declaration of Interference in or about the month of November 1902 being at that time in England.

THAT patents for such invention were applied for as follows:

Application filed in GREAT BRITAIN, May 25th, 1903, under No. 11921. Published on the 25th August 1904, Patent issued on 9th November, 1904.

Application filed in AUSTRIA on May 20th, 1904, which application was published on the 15th July, 1905, and the Patent was issued on 27th December, 1905, under No. 22567.

Application filed in GERMANY under No. F. 18896, on the 21st May, 1904, and the Patent was issued on the 2nd May, 1907, under No. 184014.

Application filed in BELGIUM under No. 141999 upon the 26th May, 1904, Patent issued on the 15th June, 1904, under No. 177505.

Application filed in HUNGARY under No. 6671 on the 28th May, 1904, Specification published 12th July, 1905, Patent issued 2nd September, 1905, under No. 33799.

Application filed in FRANCE under No. 9543 on the 31st May, 1904, Specification published 25th August 1904, Patent issued 25th August, 1904, under No. 344053.

Application filed in SWITZERLAND under No. 37595 on the 25th February, 1905, and divided from Patent No. 31796, issued on the 20th May, 1904. Specification published 26th September, 1905, Patent issued 31st October, 1905, under No. 33124.

Application filed in RUSSIA under No. 26649, on
27th April, 1905.
10th May, 1905 Allowed on the 13/26th December, 1912. Patent not yet granted.

Application filed in CANADA under No. 118355, on the 23rd May, 1905, Patent issued on the 6th November, 1906, under No. 101886.

Application filed in Italy under No. 79 on the 27th July, 1905,
100
Patent issued upon the 18th September, 1905, under No. 208, Volume 211.

Application filed in the UNITED STATES OF AMERICA under Serial No. 385056, filed 22nd July 1907, divided from application Serial No. 208034, filed 14th May, 1904. Patent issued 24th December, 1907, under No. 874398.

That his invention has never been described in a printed publication by him other than by the issues of copies of the specifications of the various patents so far published as set out hereinabove.

THAT the knowledge of this invention was introduced into the United States by the sending thereto of the papers in connection with the application for patent, which, as he is informed and does verily believe, were dispatched from London, England, on the 2nd May, 1904, by his British Patent Agents, Messrs. Marks & Clark, of 18, Southampton Buildings, in the County of London, England, with a letter to their United States correspondents: Messrs. Spear, Middleton, Donaldson & Spear, of 1003, F. Street, Washington, D. C., now of Victor Building, 9th & Grant Place, Washington, D. C., the Attorneys of Record, instructing the said Messrs. Spear, Middleton, Donaldson & Spear to file such application and solicit-

ing their services in procuring a patent therefor in the United States.

THAT he is informed that this letter with the application papers was received by the said Messrs. Spear, Middleton, Donaldson & Spear, and the application filed in the United States Patent Office on the 14th May, 1904.

THAT under the provisions of the International Convention for the protection of industrial property, to which Great Britain and the United States are parties, he claims the date of conceiving and making his invention, forming the subject matter of the present Interference in England viz., November 1902 or failing this, he claims the date of his application for a patent in Great Britain, namely May 25th, 1903, as the date of the invention forming the subject matter of the present Interference, and forming part of his "Process and apparatus for electrically welding turbine blades to their carrying elements," set out in his United States patent application Serial No. 208034 above referred to, such United States application being embodied and covered by the said British application under Patent No. 11921 of 1903, granted thereon, as is established by the certified copy of the British patent No. 11921 of 1903, now produced and shown to him, and attached hereto and marked "S. Z. de F[1]."

SEBASTIAN ZIANI DE FERRANTI.

Sworn at the Consulate-General of the United States of America at London, England, this 15th day of November 1913 before me Hubert D. Jamison, Deputy Consul-General of the United States of America at London, England.

PROVISIONAL SPECIFICATION.

"Improvements in and relating to the Electric Welding of Turbine Blades."

I, SEBASTIAN ZIANI DE FERRANTI, Engineer, of 31, Lyndhurst Road, Hampstead, London, N.W. do hereby declare the nature of this invention to be as follows:

The invention relates to improvements in and relating to the electrical welding of turbine blades to the discs or drums carrying them, and has for its object to overcome the difficulties which have been experienced in electrically welding together the two parts which differ considerably as regards their power of rising to the required welding temperature when heated at the point of junction.

The main difficulty arises through the blades and their carrying discs differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the disc, ring or the like to which it is to be secured it is found that the comparatively large volume of metal forming the disc rapidly conducts heat away from the welding point, thus preventing the temperature of the disc part rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of metal of the disc in the neighbourhood of the welding point so that approximately equal heating occurs in both faces to be welded, whereby turbine wheels with welded blades may be reliably produced in an inexpensive way.

In carrying out my invention according to one modification grooves may be cut across the edge of the ring or several grooves may run circumferentially completely round the edge, or again intersecting sets of grooves inclined to one another may be cut on the edge of the ring.

According to another modification, radial holes may be bored a short distance into the edge, either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded or arranged without particular reference to the position of the blades.

The object to be kept in mind in [illegible] as explained above, while at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Again, the result aimed at may be secured by boring holes through from face to face of the ring at a radius slightly less than that of its outside edge.

According to another modification of the invention, the ring may be built up of two or more thinner rings held in their relative positions by distance pieces or in any other convenient manner, the blades being then welded in position on their outside edges.

Again, the ring may be built up of a set of thin laminae, the edges of which are notched, the laminae being assembled in such a way that the notches

[*Price* 8*d.*]

are "stepped" with regard to each other, the intervening projections of metal thus following the shape of the turbine blades to be welded to them.

Dated this 25th day of May 1903.

COMPLETE SPECIFICATION.

"Improvements in and relating to the Electric Welding of Turbine Blades."

I, SEBASTIAN ZIANI DE FERRANTI, Engineer, of 31, Lyndhurst Road, Hampstead, London, N.W., do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:

The invention relates to improvements in and relating to methods of electrically welding turbine blades to the discs, drums or the like carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an inexpensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier rapidly conducts heat away from the welding point, thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of the blade carrying element in the neighbourhood of the welding point, so that approximately equal heating occurs in both faces to be welded.

Referring to the accompanying drawings which, with the exception of Figure 4, show the invention applied, by way of example, to a type of parallel flow turbine in which the blades are mounted on the edge of a wheel-like body,

Figure 1 is a part side elevation of such a wheel having cross grooves,

Figure 1ª being an edge view:

Figure 2 shows a similar edge view of a modification in which sets of intersecting grooves are adopted;

Figure 3 shows an edge view of a form having circumferential grooves,

Figure 4 shows, in longitudinal sectional elevation, part of a drum carrier to which the blades are welded in accordance with one form of the invention:

Figures 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disc, while

Figure 7 is a part side elevation in which holes are bored through from face to face of the disc:

Figure 8 shows a sectional plan of a form of wheel built up of two dished discs, held apart at their circumferential portions by distance pieces.

THE SEAL OF THE PATENT OFFICE

Figure 8ª being a scrap edge view to a larger scale;

Figure 9 is a similar sectional plan of a modified form of wheel built up of three discs, while

Figure 9ª is a corresponding scrap edge view also to a larger scale:

Figure 10 shows a part sectional elevation of a wheel built up of two comparatively thick discs having notched edges,

Figure 10ª being a scrap edge view, while finally

Figure 11 shows an edge view of a form of wheel built up of a series of "stepped" laminae.

It will be seen that all the edge views are shown as developments for clearness of drawing and not as true projections.

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

In carrying out the invention according to the form shown in Figures 1 and 1ª, the turbine wheel or disc is shown at *a*, cross grooves, *b*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded.

The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disc, as is shown in Figure 2, or by cutting circumferential grooves, such as *f*, completely round the edge (see Figures 3 and 3ª.)

Figure 4 shows the invention, according to one form, applied to the case of a drum blade carrier, a^1: the drum is grooved circumferentially with grooves, f^1, the intervening collars of metal being then cross-cut to form projecting teeth, c^1, on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disc, these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in Figure 5, or arranged without particular reference to the position of the blades, (see Figure 6).

In Figure 7, a method is shown of removing metal in the neighbourhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disc at a radius slightly less than that of its outside edge.

The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, whilst at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Referring now to Figures 8 and 8ª, a form of wheel is shown somewhat diagrammatically which is built up of two dished discs, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as *l*, disposed at a radius somewhat less than the maximum radius of the discs, the blades, *d*, being welded in position on their outside edges.

Figures 9 and 9ª show a type of wheel generally similar to that last described but having an intermediate plane disc, *m*, in addition to the two dished discs, *k*: a portion, *n*, of the hub, *o*, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the discs in their correct relative position may be adopted.

In Figures 8 and 9, the dished discs, *k*, are indicated as secured to the hub, *o*, by means of the inner edge of the [illegible]

In the modification shown in Figure 10 and 10ª two dished discs, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to Figures 1 and 1ª.

Again, that portion of the disc carrying the blades, may be built up of a set of thin laminae, *r*, (see Figure 11) the edges of which are notched as at *s*, the laminae being assembled in such a way that the notches, *s*, are "stepped"

with regard to each other, so that the intervening projections of metal may follow the shape of the turbine blades to be welded to them.

Instead of notching the laminae, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In an invention such as the present, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above, and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described above by way of example.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. In turbines, the method of welding the turbine blades to the element carrying them, consisting in so adjusting the volume of metal in the blade carrier in the neighbourhood of the welding point, that approximately equal heating occurs in the two parts, substantially as described.

2. In turbines, blade carrying elements having blades welded thereupon in accordance with the method claimed in Claim 1.

3. In turbines, grooving the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

4. The bladed turbine element, hereinbefore described with reference to Figures 1 and 1ª of the accompanying drawings.

5. The bladed turbine element, hereinbefore described with reference to Figure 2 of the accompanying drawings.

6. The bladed turbine element, hereinbefore described with reference to Figures 3 and 3ª of the accompanying drawings.

7. The bladed turbine element, hereinbefore described with reference to Figure 4 of the accompanying drawings.

8. In turbines, forming holes in the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

9. The bladed turbine elements hereinbefore described with reference to Figures 5 and 6 of the accompanying drawings.

10. The bladed turbine element, hereinbefore described with reference to Figure 7 of the accompanying drawings.

11. In turbines, building the blade carriers of comparatively thin parts across the non-touching edges of which the blades are welded, substantially as described.

12. The bladed turbine element, hereinbefore described with reference to Figures 8 and 8ª of the accompanying drawings.

13. The bladed turbine element, hereinbefore described with reference to Figures 9 and 9ª of the accompanying drawings.

14. The bladed turbine element, hereinbefore described with reference to Figures 10 and 10ª of the accompanying drawings.

15. In turbines, building the blade carriers of prepared laminae assembled in a "stepped" manner, substantially as and for the purpose hereinbefore described.

16. The bladed turbine element [illegible] with reference to [illegible]

DE FERRANTI

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-entitled case.

Very respectfully,
THOMAS EWING,
Commissioner of Patents.

The parties to the above-entitled interference are hereby notified that their preliminary statements are approved, and that testimony must be taken, forwarded, and printed in accordance with the published Rules of Practice of the office.

The dates of filing and the serial numbers of the applications are given, and the times for taking testimony and for final hearing are set as follows:

No testimony to be taken within thirty days.

Sebastian Ziani de Ferranti, filed Dec. 29, 1911, Ser. No. 668,464; division of application No. 208,034, filed May 14, 1904.

Testimony in chief to close March 5, 1914.

Johann Harmatta, filed December 3, 1903, Ser. No. 183,677; patented De. 3, 1912, No. 1046066.

Testimony to close April 6, 1914.

Rebuttal testimony of de Ferranti to close April 21, 1914.

Final hearing: June 23, 1914, at 11 a. m.

In the matter of the Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

To the Hon. Commissioner of Patents:

PETITION.

Your petitioner, Johann Harmatta, by his attorneys, Messrs. Townsend & Decker, respectfully shows that he is a party to the interference declared between his patent No. 1,046,066, dated De-

cember 3rd 1912, and an application filed by Sebastian Ziani de Ferranti on December 29th 1911, Serial No. 668,464, which de Ferranti application is alleged to be a division of his application filed May 14th 1904, Serial No. 208,034; that the divisional application was filed at such a date that the party de Farranti is compelled to rely upon the application of which the application in interference is alleged to be a division and in fact it has been stated by the attorneys for said de Ferranti that it is the intention to rely on said earlier application as a record date; that on December 10th 1913 your petitioner ordered a certified copy of the file wrapper, contents and drawings of the application Serial No. 668,464, as well as a certified copy of the file wrapper, contents and drawings of the application Serial No. 208,034, from which the application 668,464 is alleged to be a division; that your petitioner received a reply from the Patent Office under date of December 12th 1913 as follows:

> "The Docket Clerk reports that you are not entitled to a copy of the divisional application as de Ferranti gains no advantage by reason of such application, he being the junior party to the proceeding."

As it is necessary to rely on the parent application and as the party de Ferranti intends to rely on such application as a record date, your petitioner prays that your Honor instruct the Docket Clerk or other proper officer to furnish your petitioner with a certified copy of the file wrapper, contents and drawings of the de Ferranti application Serial No. 208,034.

Respectfully submitted,

JOHANN HARMATTA,
By TOWNSEND & DECKER,
Attorneys.

PETITION BY HARMATTA.

Sir:

The case of

DE FERRANTI

vs.

HARMATTA,

INTF. No. 36,709,

will be heard by the Commissioner on the 8th day of January, 1914, at *11:30* A. M.

The hearings will commence at ten o'clock, and as soon as the argument in one case is concluded the succeeding case will be taken up.

If any party, or his attorney, shall not appear when the case is called, his right to an oral hearing will be regarded as waived.

The time allowed for arguments is as follows:

Ex parte cases, thirty minutes;

Motions, thirty minutes, each side;

Interference appeals, final hearing, one hour each side.

By special leave, obtained before the argument is commenced, the time may be extended.

The appellant shall have the right to open and conclude in inter-

ference cases, and in such case a full and fair opening must be made.

Briefs in interference appeals must be filed in accordance with the provisions of Rule 147.

Respectfully,

THOMAS EWING,
Commissioner of Patents.

DE FERRANTI

vs.

HARMATTA.

PATENT INTERFERENCE No. 36,709.

PETITION.

ELECTRIC WELDING.

Application of Sebastian Ziani de Ferranti filed Dec. 29, 1911. No. 668,464, division of application filed May 14, 1904.

Patent granted Johann Harmatta Dec. 3, 1912, No. 1,046,066, on application filed Dec. 3, 1903.

Messrs. Spear, Middleton, Donaldson & Spear for de Ferranti.
Messrs. Townsend & Decker for Harmatta.

This is a petition by Harmatta requesting that he be given copies of application No. 208,034 of de Ferranti.

The chief clerk has written Harmatta to the effect that he was not entitled to a copy of this de Ferranti case, although de Ferranti had referred to it in his subsequent application involved in this interference, since, as the chief clerk held, de Ferranti gained no advantage by reason of this prior application.

From the dates set up in the preliminary statement of de Ferranti, it is apparent that in order to win in this interference he must rely on his original application No. 208,034, and to determine whether or not the invention covered by the issue is disclosed in said original application, Harmatta is entitled to see it, and the petition should be and is hereby granted.

BEFORE THE PRIMARY EXAMINER.

In re Interference

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

MOTION TO DISSOLVE.

NOW COMES JOHANN HARMATTA, a party to the above-entitled interference, by his attorneys, and moves that the interference be dissolved on the following grounds:

FIRST:

That the party Ferranti has no right to make the claims forming the subject of the interference for the reason that said claims are a departure from and for a different invention from that which is set forth and disclosed in the original application of which this purports to be a division, since the disclosure made in the original application is exclusively for a process of butt-welding the end of a turbine blade on to its carrier or wheel, whereas the invention claimed in the divisional application by the claims involved in the interference is for a process differing essentially from a mere butt-welding process.

SECOND:

That the party Ferranti has no right to make the claims forming the subject of the interference for the reason that they are based on new matter inserted in the divisional application, for which there is no foundation in the original application, to wit: the paragraph beginning with line 3 page 3, reading as follows:

> "It will thus be seen that on the completion of the welding operation the blades will be attached to the wheel or disk by a plurality of welds isolated from one another."

In the original application there is no foundation for claims for a process of welding surfaces to each other at isolated spots of weld as called for in the counts of the interference.

THIRD:

That the party Ferranti has no right to make the claims forming the subject of the interference by reason of the fact that, as shown by the record of his original application, papers Nos. 27, 28 and 29, he acquiesced in the rejection of claims for the same substantial invention as that for which he now seeks patent and did not make the claims in issue for that invention until more than four years after the publication of the United States Patent No. 928,701, dated July 20th 1909, to A. F. Reitzel, containing said claims, and for many years after the invention had gone into general public and well-known commercial use.

BEFORE THE EXAMINER OF INTERFERENCES.

IN RE INTERFERENCE NO. 36,709.

DE FERRANTI

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

THOMAS EWING,
Commissioner of Patents.

6—1652

This case is before me on motion by Harmatta filed May 4, 1914, to transmit a motion to dissolve.

The motion is set forth in three parts, which will be considered in the order given.

Parts 1 and 2 purport on their face to attack the right of De Ferranti to make the claims of the issue. An inspection of the reasons given, however, makes it apparent that the moving party does not contend that De Ferranti can not make the claims in the application specifically involved, but rather that said application is not a proper division of his earlier case, No. 208,034, of which he has been given the benefit in setting up the interference.

It must be held that the question here presented is not that of the right of De Ferranti to make the claims, but the sufficiency of this party's parent application as a basis for determining his *prima facie* rights. Even should the examiner agree with the moving party and conclude that the parent case does not support the issue, he could not dissolve the interference. The proceeding would con-

tinue as between De Ferranti's alleged divisional application and the patent to Harmatta. The question presented is really one of evidence and should be disposed of by the examiner of interferences in deciding the case upon its merits. The situation is substantially identical with that in the case of Struble vs. Young, 121 O. G., 339; 1906 C. D., 95. In that case the question involved was the sufficiency of an earlier application of Young to support the issue. The examiner of interferences refused to transmit, and his action was sustained by the Commissioner who stated that the question of the sufficiency of the earlier application to support the issue should be used as a basis for the award of priority. In that case reference was also made to the earlier case of Raulet and Nicholson v. Adams, 114 O. G., 1827; 1905 C. D., 55.

The third part of the motion raises the question of estoppel. This likewise is a question to be raised in the final disposition of the case, and not by dissolution. This was so decided in the case of Manly v. Williams, 21 Gourick, 85-11, not published in the Official Gazette.

The motion to transmit is denied.

Limit of appeal: May 16, 1914.

The taking of testimony is suspended.

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHN HARMATTA.

No. 36,709.

APPEAL TO THE COMMISSIONER.

The party Harmatta to the above-entitled interference hereby appeals to the Honorable Commissioner of Patents in person from the decision of the Examiner of Interferences rendered May 6th 1914 refusing to transmit to the Primary Examiner the Motion to Dissolve brought by Harmatta.

The following are assigned as the reasons of appeal:

1. It was error to refuse to transmit the first and second grounds of the Motion to Dissolve for the following reasons:

(a) The Examiner erred in holding that even should the Primary Examiner agree with Harmatta in the contention raised by grounds 1 and 2 of the Motion to Dissolve that the Examiner could not dissolve the interference.

(b) The Examiner erred in holding that the interference would continue even if the contentions raised in grounds 1 and 2 of the Motion were sustained.

(c) The Examiner erred in holding that the question presented was one of evidence for the reason that the question raised relates primarily to the right of the party Ferranti to make the claims, based on matters ordinarily passed on by the Primary Examiner and by whom such matters should be reviewed.

(d) The Examiner erred in treating the Motion to Dissolve as being the same as a motion to shift the burden of proof.

2. The Examiner erred in refusing to transmit the third ground of the Motion for the reason that that ground raises questions which should be reviewed by the Primary Examiner before the interference be proceeded with.

INTERFERENCE No. 36,709.

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

BEFORE THE HONORABLE COMMISSIONER OF PATENTS ON APPEAL FROM THE DECISION OF THE EXAMINER OF INTERFERENCES REFUSING TO TRANSMIT HARMATTA'S MOTION TO DISSOLVE.

BRIEF FOR HARMATTA.

This case comes up on appeal by the party Harmatta from the decision of the Examiner of Interferences dated May 6th 1914

refusing to transmit to the Primary Examiner the Motion to Dissolve brought by Harmatta.

The motion to dissolve embodies three grounds:

The first ground denies the right of the party de Ferranti to make the claims forming the subject of the interference for the reason that they are a departure from the disclosure made in the original application filed by de Ferranti and upon which he relies for a record date in this interference.

The second ground denies the right of the party de Ferranti to make the claims forming the subject of the interference for the reason that they are based on new matter inserted in the divisional application, for which there is no foundation in the original application from which the application in interference purports to be a division, the date of the original application being relied upon as a record date for the purpose of the interference.

The third ground alleges that the party de Ferranti has no right to make the claims for the reasons that he acquiesced in the rejection of the claims drawn to the same substantial invention in his original application and is therefore now estopped from asserting his right to these claims.

The interference is between a patentee, Harmatta, and an applicant, de Ferranti. Harmatta filed his application on December 3rd 1903, which matured into a patent on December 3rd 1912. De Ferranti filed the application involved in this interference on December 29th 1911 as an alleged divisional application of his original application filed on May 14th 1904. Both de Ferranti's original and his alleged divisional applications are still pending before the Patent Office.

The first and second grounds of the motion to dissolve, alleging departure from the original disclosure and the incorporating of new matter in the divisional, will first be discussed.

As will appear by the record of de Ferranti's divisional application, it is absolutely necessary for him to rely upon the record date of his original application in order to obtain any right whatever to make the claims forming the subject of the interference, for the reason, as will appear by such record, that there were statutory bars to de Ferranti making these claims in his divisional application if he did not have a disclosure sufficient in his original upon which to base the claims of the interference, to wit:

French patent to Egel No. 336,187, dated March 1, 1904;

British patent to Harmatta No. 22,981 of 1903;

United States patent to Rietzel, No. 928,701, dated July 20, 1909,

it being borne in mind that de Ferranti's divisional application was not filed until December 29th 1911. Incidently, we desire to state that the above Harmatta British patent and the Egel French patent make identically the same disclosure as the Harmatta United States patent involved in this interference.

These statutory bars are part of de Ferranti's official record in

the Patent Office and should be taken judicial notice of by the Examiner of Interferences.

It was necessary that the Primary Examiner should decide that de Ferranti had the right to make the claims in his original application or otherwise he would have been compelled to reject the divisional application on the statutory ground either that the invention was contained in prior patents to Egel, Harmatta and Rietzel, which were publications more than two years prior in date to the filing of the de Ferranti application, or else on the ground that the application was not filed within one year after the date of the filing of the de Ferranti foreign application, which foreign application was matured as a patent (see the British patent No. 11,921 of 1903).

The present motion merely seeks a review of that decision of the Primary Examiner. If, on review, he comes to a different conclusion, the interference would necessarily be dissolved and could not, provided his action in review stands, ever be declared again because of the existence of the statutory bars.

The Examiner of Interferences in his decision refusing to transmit these grounds of the motion to dissolve on the authority of the cases cited by him evidently treated the said grounds as either a motion to shift the burden of proof, or, in effect, that even should the Primary Examiner (it being understood that under the latest modification of the Rules the Law Examiner is substituted for the Primary Examiner) agree with the substance of the first and second grounds or either of them of the motion to dissolve and conclude that de Ferranti had no foundation in his original case for the claims of the interference, that even then he could not dissolve the interference and that the interference would still persist.

Both of the above views are entirely erroneous, in the first place with regard to the shifting of the burden of proof, because there is no such motion before the Examiner of Interferences for the reason that Harmatta is the senior party to the interference at this time, he having filed his application on December 3rd 1903 and de Ferranti did not file even his original application until May 14th 1904, so that, even should it be decided that de Ferranti had such a disclosure in his original case as would warrant the claims of the interference he would still remain the junior party, Harmatta, the moving party and by whom this appeal is taken, being under any circumstances the senior party. In the second place, should the Primary Examiner or the Law Examiner as the case may be, decide that there is no warrant for the claims of the interference in de Ferranti's original case, he would necessarily have to dissolve the interference owing to the statutory bars existing against the making of the claims in the alleged divisional application as appears by the record of said application and as above referred to. In the cases cited by the Examiner of Interferences the interference would still have persisted or would have to be re-declared should the Primary Examiner have decided that the applicant had sufficient

foundation in his original application to make the claims made in the divisional application, the divisional application being involved in the interference. Therefore, the primary reason for refusing to transmit the motion to dissolve in the cited cases was that no matter how the Primary Examiner might decide the motion the interference would persist. This is an entirely different state of facts than is present in the present case, which may be an unusual one but is nevertheless a pertinent one.

AS ABOVE STATED, IN THE PRESENT CASE THE INTERFERENCE WOULD NECESSARILY HAVE TO BE DISSOLVED IF IT IS FOUND THAT DE FERRANTI HAS NO FOUNDATION IN HIS ORIGINAL CASE UPON WHICH TO BASE THE CLAIMS OF THE INTERFERENCE.

To state the case hypothetically, assuming that the Primary Examiner decides that de Ferranti has no right to make the claims forming the subject-matter of the interference for the reason that the disclosure in his original application as filed on May 14th 1904 had no disclosure or foundation for them, the Primary Examiner would have to take judicial notice of the statutory bars in the divisional application as such bars are of record in that application and would necessarily have to dissolve the interference. As the Examiner necessarily has to take judicial notice of these statutory bars for the reason above stated, it was not necessary to specifically raise them in the motion.

Therefore, it was clear error for the Examiner of Interferences to state that the interference proceeding would continue as between de Ferranti's alleged divisional application and the Harmatta patent.

It will be found in every case reported where the motion to dissolve was not transmitted, where such motion related to an original and a divisional application, that the circumstances were such that the granting of the motion to dissolve would not necessarily result in the final determination of the conflict between the applicants or between the applicant and the patentee but that the interference would either have to be renewed or re-declared between the same or other pending applications. As far as can be gathered in each of these decisions, there was no question of the existence of a statutory bar against the making of the claims in the divisional application, of which statutory bar the Examiner would have to take judicial notice.

In conclusion, with regard to the peculiarities of the present case, it must again be reiterated here that should the Primary Examiner agree with the substance of the first and second grounds of the motion, he would necessarily dissolve the interference as part of his duty on account of the statutory bars of which he is well aware and which absolutely prevent the making of the claims in the application specifically mentioned in the interference.

With regard to the third ground raised by the motion to dissolve and relating to the question of acquiescence in the rejection of

claims and estoppel from reasserting such claims, the questions here raised are such as should necessarily be passed upon before putting the parties to the expense of an actual contest.

Under this ground is to be decided the question whether an applicant, after having previously acquiesced in the rejection of claims for the same substantial subject-matter, can again re-assert such claims after delaying for a period of more than four years after he had notice of the United States patent to Rietzel No. 928,701, which contained the identical claims made the subject of the present interference and copied by the party de Ferranti, not from the Rietzel patent, but from the Harmatta patent.

It is respectfully submitted that the Examiner of Interferences was clearly in error in not considering all the peculiar circumstances of this case which differentiate it over those cases heretofore decided and in not transmitting the motion to dissolve, and that his decision should in justice and equity be reversed.

JOHANN HARMATTA,

IN THE UNITED STATES PATENT OFFICE.

DE FERRANTI

vs.

HARMATTA.

PATENT INTERFERENCE NO. 36,709.

APPEAL ON MOTION.

ELECTRIC WELDING.

Application of Sebastian Z. de Ferranti filed December 29, 1911, No. 668,464, division of application filed May 14, 1904.
Patent granted Johann Harmatta December 3, 1912, No. 1,046,066, on application filed December 3, 1903.

Messrs. Spear, Middleton, Donaldson & Spear for de Ferranti.
Messrs. Townsend & Decker for Harmatta.

This is an appeal by Harmatta from the decision of the examiner of interferences refusing to transmit a motion to dissolve.

The first two grounds of the motion allege that de Ferranti has no right to make the claims, since his application directly involved herein is not a division, as claimed, of a prior application. The third ground alleges that for specific reasons de Ferranti is now estopped to make the claims. The transmission of the motion as to the last ground is not urged on this appeal.

The examiner of interferences refused to transmit the motion on the ground that the question was one of evidence, since so far as alleged, even if the later application of de Ferranti was not a division of the former, the interference would still exist.

The motion makes no reference to any bar to the grant of a patent to de Ferranti, but it is urged that the record shows the existence of such a bar unless the invention is disclosed in his earlier application, and that therefore if the examiner should agree with the substance of the first and second grounds of the motion, the interference must necessarily be dissolved.

If the moving party desired to urge at the hearing on the motion that certain patents constitute a bar to the grant of the patent to de Ferranti, it should have been so stated in the motion, and the examiner of interferences properly refused to transmit the motion as presented.

The question whether the invention is disclosed in de Ferranti's earlier application will necessarily be raised in connection with the question of priority, and as both parties are relying upon foreign applications and de Ferranti does not allege a date of introduction of the invention into this country prior to Harmatta's filing date, a decision that the invention is not disclosed in the earlier application would, so far as appears, result in an award of priority to Harmatta. Furthermore, there is apparently an inconsistency between the first two grounds of the motion and the third, since the question whether one application is a division of another is not dependent upon the time when claims were presented in the earlier application, but upon the disclosure of the two cases.

Under all the circumstances I do not feel justified in remanding the interference to the law examiner for consideration of the question of dissolution.

The decision of the examiner of interferences is affirmed.

AMENDMENT.

NOW COMES JOHANN HARMATTA, by his attorneys, and amends his motion to dissolve filed May 4th, 1914, in the following respects:

Change "Primary Examiner" to "Law Examiner" in the caption.

Erase the period at the end of the first and second grounds of the motion and add the following to each ground: "and statutory bars appearing of record in the case exist against such claims when made in the present application standing by itself, to wit: British Patent to Harmatta No. 22,981 of 1903; U. S. Patent to Rietzel No. 928,701, dated July 20, 1909; and French Patent to Egel No. 335,889, dated Feb. 18, 1904."

Erase the third ground of the motion to dissolve, so that said motion to dissolve as amended will read as follows:

"IN THE UNITED STATES PATENT OFFICE.

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

BEFORE THE LAW EXAMINER.

MOTION TO DISSOLVE.

NOW COMES JOHANN HARMATTA, a party to the above-entitled interference, by his attorneys, and moves that the interference be dissolved on the following grounds:

FIRST:

That the party Ferranti has no right to make the claims forming the subject of the interference for the reason that said claims are a departure from and for a different invention from that which is set forth and disclosed in the original application of which this purports to be a division, since the disclosure made in the original application is exclusively for the process of butt-welding the end of a turbine blade on to its carrier or wheel, whereas the invention claimed in the divisional application by the claims involved in the interference is for a process differing essentially from a mere butt-welding process and statutory bars appearing of record in the case exist against such claims when made in the present application standing by itself, to wit: British patent to Harmatta No. 22,981 of 1903; U. S. Patent to Reitzel No. 928,701, dated July 20, 1909; and French Patent to Egel No. 335,889, dated Feb. 18, 1904.

SECOND:

That the party Ferranti has no right to make the claims forming the subject of the interference for the reason that they are based on new matter inserted in the divisional application, for which there

is no foundation in the original application, to wit: the paragraph beginning with line 3 page 3, reading as follows:

> 'It will thus be seen that on the completion of the welding operation the blades will be attached to the wheel or disk by a plurality of welds isolated from one another.'

In the original application there is no foundation for claims for a process of welding surfaces to each other at isolated spots of weld as called for in the counts of the interference and statutory bars appearing of record in the case exist against such claims when made in the present application standing by itself, to wit: British Patent to Harmatta No. 22,981 of 1903; U. S. Patent to Rietzel No 928,701, dated July 20, 1909; and French Patent to Egel No. 335,889, dated Feb. 18, 1904.

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

AFFIDAVIT.

County of New York, State of New York, ss:

Charles F. Tischner, Jr., being duly sworn, deposes and says that he is a member of the firm of Townsend & Decker, 149 Broadway, New York, and has direct charge of this interference; that said firm is the attorney of record for the party Harmatta in the above-entitled interference; that as now appears it was inadvertence not to incorporate in the original motion to dissolve a reference to the statutory bars existing against the making of the interfering claims in the alleged divisional application of Ferranti; that said inadvertence did not appear until the Examiner of Interferences refused to transmit the motion to dissolve on the ground that even if the allegations made in the motion were correct the interference could not be dissolved and such holding upheld by the Commissioner on appeal by decision dated June 5th 1914; that the inadvertence came

about by deponent's belief that it was not necessary to specifically call the Examiner's attention in said motion to the statutory bars which would automatically and necessarily apply if the main ground of the motion were upheld and which are of record in Ferranti's alleged divisional application and that any such holding that it was necessary to refer to them in the motion, as held by the Commissioner, came as a complete surprise; that it was deponent's firm belief that the Examiner would be compelled to take judicial notice of the statutory bars appearing in the record of said Ferranti alleged divisional application and further deponent saith not.

Mailed " " "
Interference Division.

BEFORE THE EXAMINER OF INTERFERENCES.

IN RE INTERFERENCE NO. 36,709.

DE FERRANTI

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

THOMAS EWING,
Commissioner of Patents.

This case is before me on a motion by Harmatta to transmit an amended motion to dissolve.

De Ferranti is involved in the interference on an application filed December 29, 1911, which is stated in the declaration to be a division of an earlier application No. 208,034, filed May 14, 1904.

In the original motion it was alleged in substance that De Ferranti is not entitled to make the claims because the invention is not disclosed in his early application, no reference being made to the divisional application. This motion was refused transmission on the ground that the right of De Ferranti to make the claims in his application directly involved was not attacked, and hence the interference would not be dissolved even if the early application were held not to support the issue. The refusal to transmit was affirmed by the Commissioner.

The amended motion also attacks the right of De Ferranti to make the claims on the ground that the invention is not present in his early application, and in addition alleges that a statutory bar in the form of several patents exists against the second application. As now framed it is believed the motion should be transmitted. If the early application of De Ferranti does not support the issue, he must then rely upon his second application, and if this application is anticipated by the patents referred to in the motion, dissolution of the interference will result. These are questions which it is believed should be considered by the Law Examiner.

At the hearing some objection to transmission of the motion was made in behalf of De Ferranti on the ground of delay in presenting the second motion. While some delay has occurred it is noted that the amended motion was filed promptly after the decision of the Commissioner, and under the circumstances of the case it is deemed proper to transmit the same.

The motion is granted, and the interference is transmitted to the Law Examiner.

The taking of testimony is suspended.

36,709—39.

IN THE UNITED STATES PATENT OFFICE:

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

BEFORE THE LAW EXAMINER.

This case comes before your Honor on motion for dissolution brought by Harmatta, alleging that de Ferranti has not right to make the claims.

The motion to dissolve is made on two grounds: first, that the claims forming the issue are a departure from the disclosure made in the original application; and second, that the claims constituting the issue are based on new matter inserted in the divisional application for which there is no foundation in the original application.

With regard to the first ground, the applicant would state that the claims in the divisional application are in no case a departure from and for a different invention from that which is set forth in the original application from which the present application in Interference is a divisional. They are simply generic claims which include matter which applicant originally claimed specifically.

Although the disclosure in the original application was for a process of welding the end face of a turbine blade onto the face of its carrier, yet there was nevertheless present the broad invention of welding together at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

It is a well-recognized point in United States patent practice that the only limitation to the claims in an applicant's patent is the state of the art to which the application relates. This is well settled by the case of Hill vs. Hodge, 12 App. D. C., 528, wherein the court said:

> "An inventor making any generic invention necessarily produces some species of it, and the fact that he has never thought of other specific forms can not deprive him of his right to a broad claim. The inventor may not regard his invention at the time it is produced as any broader than his specific form;

but the question for consideration is not as to his opinion, but is one of fact."

See also the case of Ryder vs. Townsend, 188 F., page 807:

"And when an inventor makes an invention and in his specification points out a specific construction, he may claim the specific costruction and also have a general broad claim, and when this is in order to sustain the broader claim it is not necessary for the patentee to point out in his patent that the specific construction shown is not essential to the invention. The law gives him ample protection whether he does or not."

Although the present application discloses a process for welding turbine blades onto their carrying elements, yet the applicant submits that it is unnecessary that the claims be limited to the specific embodiment which he has shown in his specification.

In the present divisional application the claims are not limited to a process for electrically welding turbine blades to their carrying elements, but are independent of such application as the state of the art cited against this case enabled the applicant to make such claims.

It might also be stated at this juncture, that the same point was raised by the Primary Examiner during the prosecution of the divisional application, and in view of the arguments set forth he withdrew from this attitude, allowed the claims to be inserted, and declared the interference.

With regard to the alleged statutory bars appearing of record to wit: British Patent to Harmatta No. 22981 of 1903, U. S. Patent to Rietzel, No. 928701, dated July 20th, 1909, and French Patent to Egle, No. 335889, dated February 18, 1904. All of these patents are dated subsequent to the date which the applicant claims under the International Convention, viz., May 25, 1903, and in view of the fact that the applicant maintains that the present application is properly entitled to the date claimed under the International Convention, such patents are no bar in the event of the applicant's contention being upheld.

Coming now to the second ground of the motion that de Ferranti had no right to make the claims forming the subject of the Interference for the reason that they are based on new matter inserted in the divisional application, for which there is no foundation, viz., the following paragraph:

"It will thus be seen that on the completion of the welding operation the blades will be attached to the wheel or disc by a plurality of isolated welds."

while this paragraph certainly does not appear in the parent application, it is not a statement of the method, but a mere statement of what has resulted after the method has been carried out. The lan-

guage quoted "It will thus be seen that on the *completion* of *welding operation*" shows clearly that this is what follows as a matter of course from the method previously described, and the whole disclosure therein is sufficient justification for its insertion in the divisional.

The allegation of Harmatta that there is no foundation in the original application for claims for a process of welding surfaces to each other at isolated spots of weld, as called for in the counts of the Interference is at variance with the facts, as the figure in the divisional application is exactly as it stood in the original application.

Further, the following parts of the parent application as originally filed are referred to as furnishing ample foundation for and fully justifying the claims forming the issue:

On page 2, line 11, the following statement appears:

"Figure 1 is a part side elevation of a turbine wheel having *cross grooves.*"

Then at line 14:

"Figure 2 shows a similar edge view of a modification in which *sets of intersecting grooves are adopted.*"

On page 3, last three lines from the bottom, and page 4:

"In carrying out the first part of the invention according to the form shown in Figures 1 and 1a, the turbine wheel or disc is shown at *a*, cross grooves *b*, being cut in its circumferential edge *So AS TO LEAVE PROJECTING PORTIONS OF METAL c TO WHICH THE TURBINE BLADES ARE WELDED.* The SAME OBJECT is obtained by cutting two *intersecting sets of grooves c* in the edge of the disc as shown in Figure 2."

Then in the last paragraph on page 4, the following statement occurs:— "The object to be kept in mind in this, as in other modifications, is to leave sufficient metal to enable the temperature to rise to the welding point as explained above, *WHILST AT THE SAME TIME LEAVING SUFFICIENT AREAS UNTOUCHED TO ENSURE THE MECHANICAL STRENGTH IN THE WELDED JOINT.*"

It is respectfully submitted that when the above extracts from the parent application as originally filed, are considered, the contention of Harmatta that there is no foundation for the claims in the original application, is wholly untenable.

The above paragraph which refers to Figures 1 and 1a, clearly shows that the blade is to be welded to the projectinging portions of metal formed by the grooving of the circumferential edge of the blade carrier, while the same object, viz., the welding of the blades to the projecting pieces of metal, is attained when intersecting sets of grooves are cut as shown in Figure 2 of the parent application, which is identical with the drawing in the divisional application.

The disclosure in the parent application, therefore, shows a pro-

cess of electric welding in which a turbine blade is attached to a carrier by means of a plurality of welds isolated from one another, as in no other manner could a turbine blade be attached when the process illustrated in Figure 2 of the parent application is carried into effect. This being the case, the applicant, finding he was the first so far as the prior art cited by the Examiner was concerned, to weld two parts together electrically by a plurality of welds isolated from one another, he considers that he is entitled under the law and decisions to file claims covering this method broadly and independently of the particular purposes to which the method is applied.

Not only is the paragraph objected to by Harmatta completely justified by the extracts from the parent application, but there is ample foundation for the claims in the original application, and de Ferranti is entitled to the broadest claims which the state of the art will permit.

In conclusion, therefore, it is urged that de Ferranti is entitled to make the claims, that their subject matter is not a departure from the disclosure of the original application, that they are not based on new matter, and as de Ferranti is entitled to the convention date of May 25th, 1903, the patents referred to in the motion are too late to constitute a bar.

Very respectfully,

SPEAR, MIDDLETON, DONALDSON & SPEAR,
Attorneys for de Ferranti.

Hearing: 36,709—40.
November 16, 1914. M. S. D.

IN THE UNITED STATES PATENT OFFICE.

DE FERRANTI

vs.

HARMATTA.

PATENT INTERFERENCE No. 36,709.

MOTION FOR DISSOLUTION.

ELECTRIC WELDING.

Application of Sebastian Ziani de Ferranti filed Dec. 29, 1911, No. 668,464, division of application filed May 14, 1904.
Patent granted Johann Harmatta Dec. 3, 1912, No. 1,046,066, on application filed Dec. 3, 1903.

Messrs. Spear, Middleton, Donaldson & Spear for de Ferranti.
Messrs. Townsend & Decker for Harmatta.

The party Harmatta moves to dissolve the interference on the ground that the party de Ferranti has no right to make the claims forming the subject-matter of the interference. The reasons upon which the motion is based will be specifically considered later.

The party Harmatta is a patentee and the issue is in the terms of his claims 1, 2, 3 and 4, which are as follows:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

The invention upon which the interference is based is a process of electric welding which consists broadly in bringing the pieces of metal to be welded into contact and subjecting them locally to pressure and heating current so as to secure the pieces of metal together by what is known as "spot welding."

The Harmatta case shows pieces of relatively thin metal having their edges overlapped and secured together in the manner just stated. Harmatta describes his process as being particularly adapted for securing together sheets of metal used for sheet metal ware like vessels or household utensils. de Ferranti employs the process

disclosed in his case to secure turbine blades to a turbine wheel or support, although he states that his process is of general application. As shown in the de Ferranti drawing, the ends of the blades *d* are brought into contact with spaced projecting portions on the wheel or carrier and electrically welded thereto. The spaced projecting portions are designated *f* in the specification and, as shown in Fig. 2 of the drawing, are formed by intersecting grooves. As also shown in Fig. 2, one end of the blade engages a number of the spaced projections.

The de Ferranti case is set up as a division of an earlier case, Serial No. 208,034, filed May 14, 1904, and if the application involved in interference is not entitled to the filing date of the original application, it is subject to certain statutory bars, i.e., the British patent to Harmatta, No. 22,981 of 1903, the U. S. patent to Rietzel, No. 928,701, July 20, 1909, and the French patent to Egel, No. 335,889, February 18, 1904. That the patents just referred to constitute statutory bars to the grant of a patent to de Ferranti based on the application involved in this interference is admitted, unless the application is a division of the de Ferranti original application.

Broadly stated, Harmatta's motion raises two questions, that of "departure" and "new matter" when a comparison is made of the original and alleged divisional applications of de Ferranti. Thus it is contended in behalf of Harmatta that de Ferranti's original application disclosed only a process of butt welding the end of a turbine blade on to its carrier or wheel, whereas the process claimed in the divisional case differs essentially from a butt welding process. It is further contended in behalf of Harmatta that the following statement found on page 3 of the specification of the divisional case constitutes "new matter" so far as the disclosure of the original case is concerned:

> "It will thus be seen that on completion of the welding operation the blades will be attached to the wheel or disk by a plurality of welds isolated from one another."

The figures of drawing of the de Ferranti application involved in interference correspond to and are substantially identical with Figs. 1 and 2 of the original case. There is in the specification of the original case no definite statement to the effect that the end of the turbine blade is welded to the wheel or support at spots only. However, the practice of the process originally disclosed must result in spot welding broadly, unless the parts to be welded are subjected to heat and pressure for so long a time as to break down the projections on the wheel with which the end of the blade contacts and cause a fusion or coalescence of the entire end surface of the blade and that portion of the wheel with which it engages. In Fig. 1 of the drawing in both original and divisional cases and

also in Fig. 13 of the original case, all of which show the wheel after the blades have been welded thereto, the projections are not broken down but retain substantially, at least, their original heights. If this is a correct showing the conclusion seems inevitable that the blades are welded to the wheel only at spots corresponding to the projections on the wheel, as shown in Fig. 2 of both the original and divisional cases. In the original de Ferranti specification, on page 4, occurs the following statement:

> "The object to be kept in mind in this, as in other modifications, is to leave sufficient metal to enable the temperature to rise to the welding point as explained above, whilst at the same time leaving sufficient areas untouched to ensure the mechanical strength in the welded joint."

Also, on pages 3 and 4, it is stated in describing the grooves in the wheel that the grooves are cut "so as to leave projecting portions of metal *c* to which the turbine blades are welded."

The specification of the original de Ferranti application describes on page 7 and elsewhere the application of pressure to the parts to be welded. It is stated on page 10 of the original specification that as the blade softens under the heat, the pressure of a spring causes a slight shortening of the blade, i.e., the turbine blade, but there is no suggestion that the projections on the wheel or support are broken down or destroyed.

The statement is made in the motion papers that what de Ferranti disclosed in his original case was a process of butt welding and that the claims involved in the interference are for an invention differing essentially from mere butt welding. It may be said with respect to this statement that the claims, in terms at least, do not exclude butt welding but require that the pieces of metal shall be welded together at spots only of their adjacent surfaces. The limitation in the counts to localized pressure is present in de Ferranti, since obviously pressure will be exerted only on those portions of the metal pieces where the projections on the wheel or support contact with the end of the blade.

The only question before the law examiner is that of right on the part of de Ferranti to make claims corresponding to the counts. With respect to this question, it must be answered in the affirmative. The motion for dissolution is accordingly denied. No appeal lies from this decision, hence no limit of appeal is fixed.

UNITED STATES PATENT OFFICE,

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

BEFORE THE EXAMINER OF INTERFERENCES.

MOTION.

NOW COMES JOHANN HARMATTA, by his attorneys, and moves for a rehearing of his Motion to Dissolve the Interference decided by the Law Examiner December 1st, 1914, upon the grounds:

1. That a question decisive of the case and duly argued by counsel was overlooked, to wit: the principle of the patent law applicable to this case and which, had it been applied, would have necessarily resulted in a different conclusion, that is, the principle that the specification and drawings must be considered together as a whole and with reference to the art to which the invention relates and to the accomplishment of the actual practical purpose of the inventor. In this case the practical purpose of securing the turbine blade to the carrier and the securing thereof in a way consistent with the formation of a joint such as is required in the turbine art would require the actual welding of the whole face of the blade so as to make a steam-tight joint.

The paragraph in the Ferranti specification referred to in the decision of the Law Examiner cannot be taken by itself and apart from the whole purpose of the invention and the art to which it belongs, for to do so would be to interpret the patent inconsistently with the principle of law, as above laid down.

2. There was obvious misapprehension of the electric welding process as evidenced by the statement of the Law Examiner in his

decision that while the turbine blade may shorten under the action of the heat and pressure, the projections on the wheel or support will not be broken down.

3. There was obvious misapprehension of the showing made in Figure 1 of the drawings of the original application in that said Figure in the original application, as pointed out in counsel's argument at the hearing showed and the description described that the projection in this Figure is disposed transversely the entire width of the carrier or wheel.

JOHANN HARMATTA,

DE FERRANTI

vs.

HARMATTA.

PATENT INTERFERENCE No. 36,709.

MOTION FOR REHEARING.

ELECTRIC WELDING.

Application of Sebastian Ziani de Ferranti filed December 29, 1911, No. 668,464, division of application filed May 14, 1904.
Patent granted Johann Harmatta December 3, 1912, No. 1,046,066, on application filed December 3, 1903.

Messrs. Spear, Middleton, Donaldson & Spear for de Ferranti.
Messrs. Townsend & Decker for Harmatta.

The party Harmatta moves for a rehearing of his motion for dissolution which was denied by the law examiner in a decision dated December 1, 1914.

There appears to be no necessity for making the joint between the base of the turbine blade and its support steam tight, as suggested in the motion for rehearing. It may be that a loss in efficiency would result if the blade were spot welded to its support, but this presents no good reason for assuming that the projecting portions on the wheel are broken down or destroyed. There is in the orig-

inal de Ferranti specification no suggestion that the joint under consideration must be steam tight, but, on the contrary, there are distinct statements that the ends of the blades are welded to the projections, as pointed out in the decision on the motion for dissolution.

The motion for rehearing is denied.

Form B.

PROVISIONAL SPECIFICATION.

IMPROVEMENTS IN AND RELATING TO ELECTRIC WELDING.

I, Sebastian Ziani de Ferranti, Engineer, of 31, Lyndhurst Road, Hampstead, London, N. W.
do hereby declare the nature of this invention to be as follows:
("11921" and "25 MAY 1903" in margin.)

The invention relates to improvements in methods of electrically welding turbine blades to the discs or drums carrying them, and has for its object to overcome the difficulties which have been experienced in electrically welding together the two parts which differ considerably as regards their power of rising to the required welding temperature when heated at the point of junction.

The main difficulty arises through the blades and their carrying discs differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the disc, ring or the like to

which it is to be secured it is found that the comparatively large volume of metal forming the disc rapidly conducts heat away from the welding point, thus preventing the temperature of the disc part rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of metal of the disc in the neighbourhood of the welding point so that approximately equal heating occurs in both faces to be welded, and turbine wheels with welding blades reliably produced in an inexpensive way.

In carrying out my invention according to one modification grooves may be cut across the edge of the ring or several grooves may run circumferentially completely round the edge, or again intersecting sets of grooves inclined to one another may be cut on the edge of the ring.

According to another modification, radial holes may be bored a short distance into the edge, either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded or arranged without particular reference to the position of the blades.

The object to be kept in mind in this as in other modifications is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Again, the result aimed at may be secured by boring holes through from face to face of the ring at a radius slightly less than that of its outside edge.

According to another modification of the invention, the ring may be built up of two or more thinner rings held in their relative positions by distance pieces or in any other convenient manner, the blades being then welded in position on their outside edges.

Again, the ring may be built up of a set of thin laminae, the edges of which are notched, the laminae being assembled in such a way that the notches are "stepped" with regard to each other, the intervening projections of metal thus following the shape of the turbine blades to be welded to them.

Dated this 25th day of May 1903.

Form C. No. 11921.

11921

COMPLETE SPECIFICATION Date 25-5-03.

25 May, 1903.

"IMPROVEMENTS IN AND RELATING TO THE ELECTRIC WELDING OF TURBINE BLADES."

I, Sebastian Ziani de Ferranti, Engineer, of 31 Lyndhurst Road, Hampstead, London, N.W., do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

The invention relates to improvements in and relating to methods of electrically welding turbine blades to the discs, drums or the like carrying them and has for its object to overcome the difficulties which have been experienced in electrically welding together two such parts differing considerably as regards their power of rising to the required welding temperature when heated at the point of junction, so that blade carrying elements with welded blades may be reliably produced in an expensive manner.

The main difficulty arises through the blades and their carriers differing as regards their power of conducting heat away from the welding point.

In the welding of a turbine blade to the carrier to which it is to be secured, it is found that the comparatively large volume of metal forming the carrier rapidly conducts heat away from the welding point, thus preventing the temperature of the carrier rising to the required extent and causing an unsatisfactory weld.

The invention, therefore, consists broadly in adjusting the volume of the blades carrying element in the neighbourhood of the welding point, so that approximately equal heating occurs in both faces to be welded.

Referring to the accompanying drawings which, with the exception of figure 4, show the invention applied, by way of example, to a type of parallel flow turbine in which the blades are mounted on the edge of a wheel-like body.

Figure 1 is a part side elevation of such a wheel having cross grooves.

Figure 1*a* being an edge view;

Figure 2 shows a similar edge view of a modification in which sets of intersecting grooves are adopted;

Figure 3 shows an edge view of a form having circumferential grooves,

Figure 3*a* being a section on the line A A of figure 3;

Figure 4 shows, in longitudinal sectional elevation, part of a

drum carrier to which the blades are welded in accordance with one form of the invention:

Figures 5 and 6 show edge views of modifications in which holes are bored radially into the edge of the disc, while

Figure 7 is a part side elevation in which holes are bored through from face to face of the disc;

Figure 8 shows a sectional plan of a form of wheel built up of two dished discs, held apart at their circumferential portions by distance pieces,

Figure 8*a* being a scrap edge view to a larger scale;

Figure 9 is a similar section plan of a modified form of wheel built up of three discs, while

Figure 9*a* is a corresponding scrap edge view also to a larger scale;

Figure 10 shows a part sectional elevation of a wheel built up of two comparatively thick discs having notched edges,

Figure 10*a* being a scrap edge view, while finally

Figure 11 shows an edge view of a form of wheel built up of a series of "stepped" laminae.

It will be seen that all the edge views are shown as developments for clearness of drawing and not as true projections.

The same reference symbols are, when possible, used in the accompanying drawings to denote similar parts.

In carrying out the invention according to the form shown in figures 1 and 1*a*, the turbine wheel or disc is shown at *a*, cross grooves, *b*, being cut in its circumferential edge so as to leave projecting portions of metal, *c*, to which the turbine blades, *d*, are welded.

The same object is attained by cutting two intersecting sets of grooves, *e*, in the edge of the disc, as is shown in figure 2, or by cutting circumferential grooves, such as *f*, completely round the edge (see figures 3 and 3*a*.)

Figure 4 shows the invention according to one form, applied to the case of a drum blade carrier, *a*1; the drum is grooved circumferentially with grooves, *f'*, the intervening collars of metal being then crosscut to form projecting teeth, *c'* on which the blades are welded.

According to a modified form, radial holes, *h*, may be bored a short distance into the edge of the disc these holes being either arranged in patterns so as to leave intervening projections of untouched metal to which the blades may be welded as shown in figure 5, or arranged without particular reference to the position of the blades, (see figure 6).

In figure 7, a method is shown of removing metal in the neighbourhood of the welding point by boring holes, *i*, through (or partly through) from face to face of the disc at a radius slightly less than that of its outside edge.

The object to be kept in mind in this as in other modifications,

is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, whilst at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint.

Referring now to figures 8 and 8*a*, a form of wheel is shown somewhat diagrammatically which is built up of two dished discs, *k*, of comparatively thin metal, held apart at their circumferential portions by one or more distance pieces such as, *l*, disposed at a radius somewhat less than the maximum radius of the discs; the blades, *d*, being welded in position on their outside edges.

Figures 9 and 9*a* show a type of wheel generally similar to that last described but having an intermediate plane disc, *m*, in addition to the two dished discs, *k*; a portion, *n*, of the hub, *o*, is in this case made detachable so as to allow the different parts of the wheel to be assembled. Distance pieces, *l*, are indicated as before but any other convenient method of holding the discs in their correct relative position may be adopted.

In figures 8 and 9, the dished discs, *k*, are indicated as secured to the hubs, *o*, by pressing the inner edges of these discs into grooves and subsequently burnishing over the hubs to hold the discs in place.

In the modification shown in figures 10 and 10*a* two dished discs, *k*, are again employed but of thicker metal, their circumferential portions being brought into contact and cross grooves, *b*, being cut in their edges in accordance with the method described above with reference to figures 1 and 1*a*. Again, that portion of the disc carrying the blades, may be built up of a set of thin laminae, *r*, (see figure 11) the edges of which are notched as at *s*, the laminae being assembled in such a way that the notches, *s*, are "stepped" with regard to each other, so that the intervening projections of metal may follow the shape of the turbine blades to be welded to them.

Instead of notching the laminae, they may be prepared in accordance with other of the methods pointed out above, before being assembled in the manner indicated.

In an invention such as the present, it is not practicable to describe every method of carrying its broad underlying principle into effect, but the scope is sufficiently indicated by the many examples given above, and moreover it will be evident without further description, how the invention may be applied to the welding together of turbine blades and carriers of other forms than those described by way of example.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—

1. In turbines, the method of welding the turbine blades to the element carrying them, consisting in so adjusting the volume of metal in the blade carrier in the neighbourhood of the welding

point, that approximately equal heating occurs in the two parts, substantially as described.

2. In turbine, blade carrying elements having blades welded thereupon in accordance with the method claimed in claim 1.

3. In turbines, grooving the blade carrier in the neighbourhood of the welding point substantially as and for the purpose described.

4. The bladed turbine element, hereinbefore described with reference to figures 1 and 1*a* of the accompanying drawings.

5. The bladed turbine element, hereinbefore described with reference to figure 2 of the accompanying drawings.

6. The bladed turbine element, hereinbefore described with reference to figures 3 and 3*a* of the accompanying drawings.

7. The bladed turbine element, hereinbefore described with reference to figure 4 of the accompanying drawings.

8. In turbines, forming holes in the blade carrier in the neighbourhood of the welding point, substantially as and for the purpose described.

9. The bladed turbine elements hereinbefore described with refernce to figures 5 and 6 of the accompanying drawings.

10. The bladed turbine element, hereinbefore described with reference to figure 7 of the accompanying drawings.

11. In turbines, building the blade carriers of comparatively thin parts across the non-touching edges of which the blades are welded, substantially as described.

12. The bladed turbine element, hereinbefore described with reference to figures 8 and 8*a* of the accompanying drawings.

13. The bladed turbine element, hereinbefore described with reference to figures 9 and 9*a* of the accompanying drawings.

14. The bladed turbine element, hereinbefore described with reference to figures 10 and 10*a* of the accompanying drawings.

15. In turbines, building the blade carriers of prepared laminae assembled in a "stepped" manner, substantially as and for the purpose hereinbefore described.

16. The bladed turbine element, hereinbefore described with reference to figure 11 of the accompanying drawings.

Dated this 24th day of February, 1904.

BEFORE THE EXAMINER OF INTERFERENCES.

AFFIDAVIT.

County of New York, State of New York, ss:

Chas. F. Tischner Jr. being duly sworn, deposes and says that he is a member of the firm of Townsend and Decker, 149 Broadway, New York, attorneys of record for the party Harmatta in the above entitled interference; that the Harmatta patent No. 1,046,066 involved in this interference is being litigated in the Courts and that the claims of Harmatta's patent made the counts of this interference are before the Courts for adjudication; that a decision of the United States District Court for the District of Massachusetts has been rendered by which the Court held the claims of the patent, including the counts of this interference, invalid for want of invention over the prior art (see Thomson Electric Welding Company et al vs. Barney and Berry, Inc. opinion of the Court dated March 10th, 1915, copy of which is attached hereto); that an appeal has been taken from said decision to the Circuit Court of Appeals for the First Circuit; that said appeal was heard by the Court on April 28th, 29th, and 30th, 1915 but that no decision of the Court has as yet been handed down; that it is impossible to determine exactly when the decision will be made but it is improbable now that it will be before October; that the reason for requesting the extension of time for taking Harmatta's testimony in the interference is that the parties should not be required to go to the expense of acually contesting the right to claims which are awaiting determination as to their validity by a Court of last resort especially in view of the decision of the lower Court against the validity of the claims and that the request is not made for any purpose of delay except that specified.

No. 434.

THOMSON ELECTRIC WELDING CO., et al.

vs.

BARNEY & BERRY, Inc.

ON PLEADINGS AND PROOFS.

OPINION OF THE COURT,
March 10, 1915.

DODGE, J.—

The Thomson Electric Welding Co. owns U. S. Patent No. 1046066, for improvements in electric welding, issued to Johann Harmatta December 3, 1912, upon his application filed December 3, 1913. It acquired Harmatta's rights in February, 1912, while his application was still pending. The other plaintiff, Universal Electric Welding Co., is and has been since 1909 exclusive licensee under all patents then or thereafter owned or controlled by the Thomson Co., including the patent whereon the present suit is brought.

There are 21 claims in all, the first 16 being for a method or process described, and the last 5 for the product thereof. Infringement of all the claims is charged, but the plaintiffs ask the Court to consider only 8 of the process claims (Nos. 3-6, 8, 9, 11 & 12) and only 4 of the product claims (Nos. 17, 18, 19, 21). The defences are, lack of invention, anticipation, invalidity because of changes made in the application before issue, and non-infringement.

Introductory statements in Harmatta's specifications are that his invention relates to the manufacture of metal articles of all kinds and consists in a novel method of fastening their component

parts together by the process of electric welding; also in the new article produced thereby. The invention is further said to afford a cheap and practical substitute for riveting.

Consideration of former methods of uniting metal by electric welding is therefore required in order to determine the precise scope of Harmatta's invention. For the purposes of such inquiry, his own definition of "electric welding" may be adopted. He says in his application,

"By the term 'electric welding' as used herein I mean that well known process in which the work is brought to the welding temperature by internal heat generated by the resistance of the work itself to the passage of an electric current at the place of contact between the parts to be joined by the welding pressure,"

and this is immediately followed by his express disclaimer of

"Those processes of fastening pieces of metal together in which the parts are heated and practically melted down by an electric arc generated on the back of the piece by 'drawing' an arc by means of the electrode, as well as other processes in which the welding heat is generated externally and electrically in a resistance material and is imparted to the work by heat conduction from said resistance material in contact with the work."

The electric welding art may be said to have begun with the inventions of Elihu Thomson, disclosed in two U. S. Patents issued to him on Aug. 10, 1886,—Nos. 347140 and 347141. The first of these describes the process of "butt-welding", wherein the ends of wires or bars, held by suitable electrodes, are butted together under pressure, raised to welding heat by an electric current of small voltage and large volume passed through them from one electrode to the other, and caused to unite into one mass over their entire area of contact, while thus plastic, by the pressure applied. A slight burr or flange of metal, extruded while plastic at the junction point, is left in the welded article. The second of the above patents covered the apparatus for carrying out the process described in the first.

Five years later (Jan. 20, 1891) another U. S. Patent No. 444,928, was issued to Thomson; covering a process of joining two strips, sheets, plates or bars of metal by continuous electrically welded seams. Roller electrodes were used, between which the two strips or sheets to be joined were fed during the passage of current from one to the other. Suitable pressure devices enabled opposed electrodes to hold the two strips or sheets in close contact between them at the point of the current's passage. The use of roller electrodes permitted an uninterrupted current to be passed through all points within the line of the desired seam successively

and without relaxation of the pressure. Electrodes not provided with means to permit this could not have produced a continuous seam, but only, at most, a series of more or less frequent welds along its line, each requiring separate application and interruption of pressure and current.

A still later U. S. Patent to Thomson,—No. 496019, issued April 25, 1893, covered a process of soldering (instead of welding) two overlapped sheets of metal together by the passage of current through them, so as to produce the necessary heat where the desired junction was to be made, between two electrodes arranged to hold them there in contact while the current passed. Less heat and therefore less current is required for soldering than for welding. The process described in this patent might have been used to produce a welded instead of a soldered union between the sheets merely by an increase in the amount of current passed between the electrodes.

All the above patents have belonged to the Thomson Co. since their issue. The two "butt-welding" patents expired Aug. 10, 1903, shortly before Harmatta's application was filed. There was reference to them and to others of the above patents in the patent in suit, made in connection with the patentee's statements of the scope of his invention.

The patent states that in general terms the invention may be said to consist.

"In fastening the pieces together by an electric weld at one or more distinct or well defined spots, each of small area or extent in their juxtaposed or opposite plane faces, by the application of pressure and heating current localized in such spots, and in the special method of localizing the heating and pressure in the spot or spots as hereinafter described," &c.

The substance of the description then following is contained in the following passage quoted from the plaintiff's brief.

"Harmatta's invention may be done described:

Two comparatively thin sheets of metal can be joined together by one or more isolated welds in their meeting surfaces made by applying electrodes of limited facial area to the backs of the sheets, pressing the electrodes and sheets together, and passing a welding current from one electrode to the other, whereby a weld is made between the sheets at the spot, the area of which is determined by the area of the electrodes in contact with the metal sheets."

The patentee's references to former patents are:

"It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces.

It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces."

"I am also aware of patent to H. F. A. Kleinschmidt, No. 616436, dated December 20, 1898, and do not wish to be understood as claiming anything disclosed in said patent."

The patent here referred to does not appear to have belonged, like the others, to the Thomson Co., but to the Loraine Steel Co. whereof Kleinschmidt was an employee. In using his patented method commercially, however, he testified that he used an electric welding machine made by the Thomson Co. His patent covers a process of attaching splice bars to rails. Two splice bars, each having on one side three projections or "bosses", one at each end and one in the middle, are placed, one bar against each side of the abutted rails, so that their projections are opposite each other and their middle projections opposite the junction of the rails. Their contact with the rails is through their projections only. Electrodes of much greater facial area than the projections are applied against the backs of the splice bars opposite each pair of projections. Pressure applied to the electrodes in the direction necessary to force them toward each other, holds the webs of the rails and the splice bar projections in contact with the electrodes and each other; the required current transmitted between the electrodes heats the projections and so much of the webs of the rails as lies between them at the contact points, the welding heat, and the pressure applied as above causes union at those points.

To the remaining patents in evidence as part of the prior art, briefer reference will be sufficient. Of U. S. Patent 363320 to Bernardos and another May 17, 1889; and the German Patent to Benardos 50509, Feb. 19, 1890, it is enough to say that neither relates to electric welding in the same sense of the patent in suit, and that both processes described are of the kinds expressly disclaimed by Harmatta, as above.

U. S. Patent No. 670808 to Perry, March 26, 1901, covers a method and machine for electrically welding the rods or wires of metallic fencing at their crossing points, by a simultaneous application of mechanical pressure and electrical current at those points. The similarity of what is described to the process of the patent in suit is at most general and not more significant, for the purposes of the questions presented, than in the case of the Thomson and Kleinschmidt patents already mentioned.

U. S. Patent to Hunter, No. 690958, Jan. 14, 1902, is for a method of electrically welding together similar sheets of metal at their ends so as to produce water-tight joints between them and from them continuous lengths for roofing purposes. Pressure and current are simultaneously applied to melt and unite the metal of the sheets at a series of points determined by projections previously

formed in one and arranged to contact with the other sheet along the desired line of junction. The metal, melted where each projection contacts with the other sheet, spreads to unite with that at the next projection and thus to form a full transverse weld. No such spreading of molten metal is contemplated by the process of the patent. Except that metallic sheets are to be joined instead of rails, I find no resemblance in this process to that of the patent more significant than in the case of the Kleinschmidt patent.

The plaintiffs say that Harmatta's method of joining comparatively thin sheets of metal by isolated welds, made in the manner described, "was a radically new idea."

But so far as he did no more than employ simultaneously the passage of electric current to bring the work to welding temperature at the place of contact by its own resistance, and application of welding pressure at the same place, he introduced no idea at all. All this, if not necessarily involved in the terms of his own definition of "electric welding", is certainly to be found in each one of the inventions disclosed in the various patents before mentioned which make use of that process. His new idea, if any, must be something beyond this.

The plaintiffs contend that localizing the current by pressure in a particular limited area of the contacting surfaces of the work, determined by the area of the applied electrode, and thereby bringing that limited area to a welding temperature without material heating of the adjacent parts, was new with Harmatta. It is said that by localizing the pressure at the selected limited area of the work, he thereby reduced the resistance, concentrated the current and increased its welding power within that area; securing at the same time, by means of the pressure upon the softened metal within the same area, the desired molecular union there between the two sheets. But all this is necessarily accomplished at every point successively along the line of the continuous electrically welded seam made by the process of Thomson's patent No. 444,928. It must also be accomplished, so far as I can see, in every case of an electric weld covering less than the whole area of the surfaces joined, made under pressure exerted between the two electrodes. The passage of current and heating of the metal must occur at those places within which the resistance is most diminished by the pressure. Claims drawn upon the theory that such localization of pressure, current and heating were new with Harmatta appear to have been repeatedly rejected and cancelled in the Patent Office before his patent issued.

The prior art thus leaves no room, so far as I can see, for crediting Harmatta with any idea beyond that of making his electric welds small in area, rather than large, in comparison with the areas of the opposed surfaces to be joined, and isolating them so as to leave each surrounded by a comparatively large area of unwelded surface. Although his patent states that a weld formed by his

process is distinguished from prior welds, "among other things," in the above respects, these are the only respects which he specifically mentions and they are in my opinion the only respects in which any distinction can be said to exist.

It is difficult to regard the above as an inventive idea. Referring again to the Thomson patent No. 444,928, the process therein described, which it is said to be "especially applicable to the welding of plates together at their edges, instead of riveting," is just as applicable to the welding of plates or sheets at other places within their area as at their edges. The roller electrodes employed, when brought together on each side of the work, and until something more is done, will pass the elctric current and make the weld at the spot or point of pressure and nowhere else. (See claim 1 of the patent referred to.) If, having there made the weld, they should be again separated, instead of having the work fed between them while their pressure upon it continued, they would leave an isolated spot weld joining the plates and be in readiness to make another weld isolated from the first by any desired area of unwelded surface.

The plaintiffs say that although machines were built to carry out the roller process of the last mentioned patent, they were not practically successful and that the process has proved a failure so far as commercial success is concerned. Their evidence tends to support this contention and to show that there are practical difficulties attending the use of the process. But so far as the question raised is important, I think the plaintiffs' evidence tending to show want of success is fully met by that of the defendant; according to which the process has been successfully carried out by machines built and commercially installed by at least two different concerns. Samples of the work they have produced by using it are among the exhibits in the case and there is nothing to show that such work is unsatisfactory in character.

The presumption of validity arising from the issue of the patent seems to me entitled in the present case to less than the usual weight in view of the history of the Patent Office proceedings upon Harmatta's application, as disclosed by the file wrapper and contents in evidence. As has appeared, the application was pending for ten years before the patent issued. As originally filed, the application described a process of roller welding substantially like that of Thomson, with the statement toward the close of the specification that instead of introducing the piece to be welded gradually between the electrodes, the welding apparatus might be arranged to slide relatively to them; and that if required to weld sheets only at particular places, apparatus employing electrodes having the form of pins might be used, instead of the roller electrodes, to produce "a small, round, very sharply defined place of welding", answering the purposes of a rivet. There were two claims covering roller welding and two others not thus limited. The idea of roller welding thus appears to have been, with Harmatta, the foundation and

origin of his further idea of spot welding; and his further idea to have consisted in nothing more than stopping with the first point welded instead of continuing it into a welded line.

Harmatta's roller-welding claims having been rejected in view of Thomson's patent, and cancelled on May 14, 1904, with so much of his original specification and drawings as related to them his application became and thereafter continued to be an application covering "spot welding" only. The original claims covering it, however, soon disappeared and there were further successive rejections, cancellations, amendments and substitutions of new claims, in 1904, 1905, 1906, 1907 and 1910. Meanwhile patent No. 928,701 issued on July 20, 1909, to Rietzel, on an application owned by the Thomson Co. March 31, 1910, Harmatta copied some of the Rietzel claims, at the suggestion of the Patent Office, in order that an interference might be declared. After this had been done, on April 26, 1910, Harmatta added still other Rietzel claims to his application and it was acquired also by the Thomson Co., pending the interference, in February 1912. The interference was decided in his favor in October 1912, but before the issue of the patent, still another cancellation and substitution of a new specification, with new claims was found necessary, wherein the invention was for the first time stated to consist in having the welds small and surrounded by comparatively large areas of unwelded surface.

All this may be regarded as significant on the question of patentable novelty (Richmond v. Atwood, 48 F. R. 910, 913); and it seems sufficient to indicate, at least, that only with unusual difficulty was Harmatta able to suggest or the Patent Office to find in his spot welding process, however described, anything capable of being regarded as patentably new in view of the prior art.

Under its butt-welding patents and roller welding patent the Thomson Co. appears to have had a complete monopoly of electric welding. The latter patent expired Jan. 20, 1908. While the monopoly continued, electric welding machines could be had only under lease from the Thomson Co., restricting their use to specified articles. In 1908, the Toledo Electric Welder Co., which made the machine which the defendant uses, and is defending this suit, began to make and introduce machines for spot-welding. Other concerns followed in 1908, 1910 and 1911, all acting without knowledge of previous applications by Harmatta or others for patents covering the spot-welding process. Under these circumstances it can hardly be said that, upon the question of patentable novelty in anything invented by him, Harmatta is supported by any advantages which the development of spot welding since 1908 has shown to reside in the process, or by any commercial success it has attained. I do not think the facts shown entitle him to say that by his alleged invention, as he was finally obliged to define and limit it, he was the first to supply a wide spread demand not previously met.

The defendant's use of the Toledo machine which is here com-

plained of as an infringement, is in the manufacture of skates. The greater part of the work done by the machine is in uniting two strips of metal, each forming half of a skate runner, by successively made, contiguous, overlapping, spot electric welds, small in size, which together make a practically continuous weld from one end of the runner to the other. The process is carried on with such rapidity that one weld has hardly begun to cool before the welding adjoining is made. The completed row of welds is thus, for all practical purposes, like a continuous seam weld produced by the use of roller electrodes. The welds of which it is composed are neither isolated nor separated by comparatively large areas of unwelded surface. I do not see how, in any case, the patent could be so construed as to make this method of welding an infringement. If not, to sustain the patent involves leaving the question of infringement to depend merely upon the amount of unwelded area left between the welds; and this result seems to me to afford a further reason against holding it valid.

My conclusion must be that the process described in the patent does not involve invention, in view of the prior art. There may be a decree dismissing the bill, with costs.

Attention of MR. STAUFFER,
Exmainer of Interferences.

SIR:

Re: Interference de Ferranti vs. Harmatta, No. 36,709.

We enclose herewith stipulation for an extension of Harmatta's

time for taking testimony in this case for a period of thirty days from the date now set.

The writer spoke to Mr. Stauffer in Washington the other day and explained this matter to him but on that day an opinion was handed down by the Court of Appeals for the First Circuit in the infringement suit referred to in the writer's affidavit accompanying the stipulation dated August 10th 1915. In this opinion the Circuit Court of Appeals reverses the lower court and holds the claims of the Harmatta patent involved in this interference valid. As explained to Mr. Stauffer at that interview, the time is now so short, even though the decision has already been rendered, for us to prepare our case for the interference as we have not yet had an opportunity to thoroughly examine the opinion of the Court, it will be impossible for us to prepare and take our proofs within the time now set. As understood by the writer, Mr. Stauffer consented to the granting of a further extension under the circumstances.

Very respectfully,

TOWNSEND & DECKER.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

MOTION TO DISSOLVE.

NOW COMES JOHANN HARMATTA, a party to the above-entitled interference, by his attorneys, and moves that the interference be disolved on the ground:

That the United States patent issued to Sebastian Ziani de Ferranti, one of the parties to this interference, on the 27th day of July 1915, No. 1,148,221, for Process of Electrically Welding Turbine Blades, constitutes a bar to the grant of a patent to said de Ferranti on the subject-matter of this interference for the reason that the invention covered by the aforesaid patent is the same as the invention covered by the application of de Ferranti as involved in this interference: that the claims of the interference as made by de Ferranti are based on the same disclosure as that of the aforesaid patent and that the disclosure of the application upon which Ferranti is now seeking a patent is in no manner different from or additional to the disclosure of said patent: that the claims in the said patent and the claims forming the counts of this interference merely differ in scope and for that reason a patent could not be granted to de Ferranti on his application involved in this interference for the

reason that it would be a mere double patenting of the invention patented by said issued patent No. 1,148,221.

Interference Division.

BEFORE THE EXAMINER OF INTERFERENCES.

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,
THOMAS EWING,
6—1652 *Commissioner of Patents.*

This case is before me on motion by Harmatta filed October 28, 1915 to transmit motion to dissolve.

The interference has been pending over two years and the motion comes therefore long after the time allowed by the rule for the presentation of motions of this character. Harmatta is involved upon patent No. 1,046,066. He moves to dissolve on the ground that De Ferranti has already obtained a patent for what is in substance the same invention as that involved herein and that it would be double patenting to grant the same party another patent for the subject-matter of this interference.

Transmission is objected to because of the delay in bringing the motion. It appears that patent No. 1,148,221 upon which motion is based, issued July 27, 1915. The present motion was not brought until three months after. There is no sufficient excuse why the motion could not have been presented earlier. Transmission is also objected to on the ground that Harmatta should not be permitted to urge the question of double patenting, but rather that this should be regarded as an *ex parte* question between De Ferranti and the office.

It seems to me that both objections are well taken. With respect to the first objection, it must be held that no sufficient explanation is given for the failure to bring the motion earlier. With respect to the second objection, it must be held that this is also well founded. De Ferranti is an applicant and he is entitled to contest with Harmatta the question of priority of invention. Even if as contended he has no right to a patent upon the application involved herein, there is apparently no reason why he may not at once file an application for the reissue of his patent No. 1,148,221. If Harmatta's contention is well founded to the effect that the subject matter of that patent and the subject matter herein issued are substantially the same, apparently the residue could be allowed.

Motion to transmit is denied.

Limit of appeal, November 17, 1915.

The taking of testimony is suspended.

In re Interference:

DE FERRANTI

vs.

HARMATTI.

No. 36,709.

APPEAL TO THE HON. COMMISSIONER OF PATENTS.

The party Harmatta to the above-entitled Interference hereby appeals to the Honorable Commissioner of Patents in person from

the decision of the Examiner of Interferences rendered November 6th 1915 refusing to transmit to the Law Examiner the motion to dissolve brought by Harmatta.

The following are assigned as the reasons of appeal:

1. The Examiner was in error in refusing to transmit the motion to dissolve on the ground that no sufficient reason was given as to why the motion could not have been presented earlier.

2. The Examiner was in error in refusing to transmit the motion to dissolve on the ground that the question raised by the motion is merely an ex parte question between de Ferranti and the Office.

3. The Examiner was in error in refusing to transmit the motion to dissolve on the ground that Ferranti could obtain a reissue of his patent No. 1,148,221 referred to in the motion.

4. The Examiner was in error in refusing at all to transmit the motion to dissolve.

Rec. Vol. 118, Page 306.

DE FERRANTI

vs.

HARMATTI.

INTERFERENCE No. 36,709.

The office has no jurisdiction to try out a question of priority where one of the parties is a patentee unless the other party, if successful, is entitled to a patent; for a proceeding by an applicant who is not entitled to a patent conducted with the aim of establishing priority of invention over the patentee would be a mere attack upon the validity of the patent which must be made, if at all, in defense of a suit for infringmen.

If it should be established that de Ferranti may not obtain a patent upon the present application because the subject-matter thereof is the same as that of his patent, he could perhaps cover the same matter by a reissue application, but an interference can be declared only after the reissue application has been filed.

As to Harmatta's delay in bringing the motion, the fact that his patent was held invalid in the district court in Massachusetts, and that the appeal heard last April was not decided until October is regarded as a sufficient excuse. Had the lower court been sustained, there would be nothing to fight about.

The decision of the Examiner of Interferences is sustained.

November 19, 1915.

Sir:

The Case of

DE FERRANTI
vs.
HARMATTA

APPEAL ON MOTION.

Interference No. 36,709, will be heard by the Commissioner on the 2nd day of December, 1915.

The hearings will commence at ten o'clock, and as soon as the argument in one case is concluded the succeeding case will be taken up.

If any party, or his attorney, shall not appear when the case is

called, his right to an oral hearing will be regarded as waived.

The time allowed for arguments is as follows:

Ex parte cases, thirty minutes;

Motions, thirty minutes, each side;

Interference appeals, final hearing, one hour each side.

By special leave, obtained before the argument is commenced, the time may be extended.

The appellant shall have the right to open and conclude in interference cases, and in such case a full and fair opening must be made.

Briefs in interference appeals must be filed in accordance with the provisions of Rule 147.

Respectfully,

THOMAS EWING,
Commissioner of Patents.

U. S. Patent Office.

UNITED STATES PATENT OFFICE,

BEFORE THE HONORABLE COMMISSIONER OF PATENTS ON APPEAL.

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

BRIEF FOR HARMATTA.

This case comes up on appeal before your Honor by the moving party Harmatta from the decision of the Examiner of Interferences dated November 6th 1915, refusing to transmit the motion to dissolve filed October 28th 1915 by the party Harmatta. Transmission of the motion was refused first, on the ground of delay in presenting it and second, on the ground that the question raised by the motion, that is, double patenting, should be regarded as an ex parte question between de Ferranti and the Office.

STATEMENT OF THE CASE.

Harmatta, the senior party to the interference, is a patentee, and de Ferranti, the junior party, is an applicant, he having copied cer-

tain broad claims from the Harmatta patent No. 1,046,066 involved in this interference for the purpose of contesting priority thereof with Harmatta. Harmatta's patent involved in this interference was issued on December 3rd 1912 on an application filed December 3rd 1903. De Ferranti's application involved in this interference was not filed until December 29th 1911 as an alleged division of an earlier application of his filed May 14th 1904. The claims of the interference are for a process of electric welding now broadly known as "spot welding." On July 27th 1915 de Ferranti, the junior party to this interference, had issued to him a United States patent No. 148,221 for Process for Electrically Welding Turbine Blades, this being the patent issued on the original application of which Ferranti's application directly involved in this interference is alleged to be a division. Figures 1 and 2 of this patent are the same as the figures of the Ferranti application in the interference. The claims of the patent are for a process or method based on the disclosures of Figures 1 and 2 which are also the subject of the pending application.

The substance of the motion now brought by Harmatta to dissolve the interference is that the issuing of a patent to de Ferranti for the invention claimed in his application declared to be in interference with Harmatta would effect a double patenting of the invention already patented to de Ferranti by his Letters Patent No. 1,148,221.

DELAY IN PRESENTING MOTION.

De Ferranti, the junior party, has closed his proofs but has not actually taken any testimony, he having merely introduced a certified copy of a British Provisional application alleging to disclose the subject-matter of the interference, so that it cannot be contended that Ferranti has been put to any material needless expense in trying out the question of priority which could lead to the contention that the interference should be decided on priority and not dissolved.

The time for taking Harmatta's case has not yet terminated but likewise he has not yet actually taken any testimony. While the interference may have been pending for a period of two years, it having been declared on the 7th of October 1913, yet, nevertheless, the present motion could not have been brought within the time called for by the rules for the reason that the Ferranti patent which warrants the bringing of the motion was not issued until July 27th 1915. Harmatta's attorneys became aware of the issuance of this patent about the first part of September 1915 but at this time the interference practically stood suspended for reasons which appear of record in this case, to wit: The Harmatta patent involving the claims of this interference was being construed by the United States Courts as to its validity and a decision of the United States District Court had already been rendered declaring all the claims of the patent invalid for want of invention over the

prior art. An appeal from that decision was filed and argued in April of the present year and the decision of the United States Circuit Court of Appeals was not yet handed down but was being awaited from day to day. Having a decision against the validity of the claims, it did not seem justice to compel prosecution of the interference at least until the nature of the decision of the Court of Appeals was learned, especially as the appeal had been argued some time before and the result thereof was daily expected. For this reason Harmatta was obtaining extensions of his time for taking his case in this interference and, as above stated, at the time of knowledge of the issuance of the Ferranti patent, to wit: September, the interference was practically suspended.

In the early part of October 1915 the opinion of the Circuit Court of Appeals on the Harmatta patent was handed down, by which opinion the Court reversed the decision of the lower Court and held the claims valid. The attorneys for the party Harmatta immediately then took up the interference for active prosecution and, it being concluded that the issuance of the aforementioned patent to Ferranti formed a complete bar to Ferranti's obtaining a patent on the subject of his present application, the present motion to dissolve was filed on October 28th 1915.

It is thought that under the circumstances of the case the delay is not an unreasonable one and is not one which Harmatta should be chargeable with. Even though there may have been some delay in presenting the motion, the delay at most has not been a very material one which can, in justice, be charged against Harmatta. The fact remains that the parties have not as yet been put to any expense of actually contesting the interference and, as it is the strenuous contention of counsel for Harmatta that the Ferranti patent already issued absolutely prevents him from obtaining a valid patent on the subject of the interference, it would be an injustice and cause the expenditure of needless moneys and time to continue the interference.

Merits of the Motion to Dissolve.

As the Examiner of Interferences has also refused transmission of the motion for reasons affecting the merits thereof, it is thought advisable to at this time refer in as brief a manner as possible before your Honor to Harmatta's contentions as to why or how the Ferranti patent referred to forms a complete bar to the obtaining of a patent by Ferranti on the subject of the interference. In the issued patent Ferranti describes and claims a certain method of electrically welding turbine blades to their carrying element. In his application involved in this interference he claims the method of electric welding which is based on the same identical process as that claimed in the patent, the wording of the claims of the application, however, being different than the wording of the claims of the patent although both are drawn to processes. The claims of the application are broader in scope than those of the patent and if

granted in a patent to Ferranti with a construction broad enough to cover the process he discloses, would be to grant to Ferranti an extension of the monopoly previously granted to him by his issued patent No. 1,148,221.

It is absolutely correct to say that in his patent No. 1,148,221 referred to in the motion, Ferranti claims his same substantial method or process that he claims in his application in interference and that there is no difference in the two methods to be inferred merely because in the patent he defines the process by reference to the result of welding onto the projections. In other words, in the application in interference the invention claimed is a method or process of welding done by welding to projections while in the patent the method or process is identified by the necessary physical action which takes place in the operation of welding to the projections.

In reaching a satisfactory conclusion on this matter it must be borne in mind that the drawings and specifications of the application and patent are substantially alike; that the one describes no other or different operation than that described and set forth in the other; that the two are based upon the same identical original application; that they do not bear the relation to one another of invention and improvement; that the claims, though in different words, refer to exactly the same practical operation and are founded upon the invention as disclosed in the original application and that the patent claim differs from the application claim only in describing a function of the operation omitted from the application claim. Assuming that it were true, which does not appear to be the case, that one might perhaps modify the operation as claimed in the application so that the normal equalization of the heat capacity would not take place, it nevertheless remains true that no such suggestion or modification of operation is in any manner suggested in either specification or in the drawings of either case. In other words, *the process or operation patented by the patent is the same as that which the applicant seeks to patent by the application.*

It seems to us clear that the matter sought to be covered by the patent is inseparably involved in the matter sought to be covered by the application; that the patent and application are in fact for the same substantial invention and that the circumstances of this case are exactly parallel to the leading cases of Thomson-Houston Electric Co. vs. Housic Railway Co., 82 Fed. 461, Circuit Court of Appeals, 2nd Circuit, Thomson-Houston Electric Co. vs. Jeffrey Mfg. Co., 101 Fed. 121, C. C. A., 6th Circuit, which have been followed in numerous other cases and which were founded upon decisions of the Supreme Court of the United States rendered on substantially the same state of facts in the case of Miller vs. Mfg. Co., 151 U. S. 198. We also cite:

Plummer vs. Sargent, 120 U. S. 442;
Lock Co. vs. Mosler, 127 U. S. 354;
McClain vs. Ortmeyer, 141 U. S. 419;

Palmer Pneumatic Tire Co. vs. Lozier, 90 Fed. Rep 732;
Thomson-Houston Co. vs. Black River Co., 124 Fed Rep. 501;
Malby Electric vs. Thomson-Houston, 148 Fed. Rep. 845;
Thomson-Houston vs. Western Electric, 158 Fed. Rep. 813.

Under the authority of these cases the Patent Office is confronted with the condition that de Ferranti has now obtained a patent for the actual invention for which he is seeking a patent by the application in interference and that said patent must stand as an effectual bar to the grant of a patent upon the application. In principle the circumstances and conditions now confronting the Commissioner on the state of facts arising from the act of the applicant in taking the patent are in no wise different than they would be if it should be discovered that the invention had been patented to some other person or even to the applicant himself by a previous patent granted prior to any date of invention appearing in this record either by the application on record or by allegation of the preliminary statement and that both parties now having obtained a patent it is the plain duty of the Commissioner to terminate this interference, leaving the party Ferranti to take such step or steps as he may be advised are necessary in order to protect his rights. It was suggested, by counsel for Ferranti at the hearing below, that the difficulties of the situation might be cured by the filing of a disclaimer, but what kind of a disclaimer would be applicable to these circumstances and whether or not the case is one for disclaimer under the law, or whether in fact a disclaimer in one of two patents conflicting in being for the same invention would operate to make the other valid, and whether or not any actual disclaimer has been filed or will be filed, are matters upon which the Commissioner is not called upon to pass at this stage of the case or under the status of the record as now presented to the Commissioner. What the applicant may choose to do lies wholly within his own mind and is subject wholly to future action on his behalf. It does not seem to us proper that the Commissioner should endeavor to anticipate that action either in respect to the matter of disclaimer or in respect to the possibility of a reissue as suggested by the Examiner of Interferences. The applicant has not filed a reissue and whether he will do so or not is a matter resting wholly in the fututre upon his own will and upon some approved course of action to be determined upon by himself or his attorneys.

The fact is that the patent stands at present as an effectual bar to the grant of a patent to Ferranti upon the application and it is not to be supposed that the Commissioner will decide the present matter upon the facts before him by endeavoring to anticipate which of two courses of action the applicant may take to remedy the difficulty in which he has placed himself, if indeed there be any difficulty, or by endeavoring to anticipate what decision he would render in the case of some disclaimer the actual nature of which can

only be disclosed when the disclaimer is filed, or what his action would be in case the applicant should file an application for reissue, the actual nature of such reissue or the grounds upon which it should be sought being only before the Commissioner in shape for his decision when the reissue application is actually filed.

Neither the above suggestion of de Ferranti's attorney nor the suggestion of the Examiner of Interferences can be adopted as a ground for a decision upon the present state of facts, for it would require the Commissioner to speculate as to the nature and effect of some future action of the applicant de Ferranti.

Aside from any question of delay, this case is one plainly calling for the exercise of the supervisory power of the Commissioner to prevent the carrying on of an entirely useless proceeding in view of the circumstances now existing and making a condition of affairs brought about solely by the action of the applicant Ferranti himself. Only by resort to speculation as to what applicant might do or what might be legally done and by making this case practically a moot case, can there be found any justification for continuing the present proceeding upon the existing state of facts.

Some suggestion has been made that the objection that the invention covered by the patent and that covered by the application are inseparably involved may be avoided on some theory that the patent is for a method of attaching turbine blades and that in the application claim no reference is made to attaching turbine blades. In our view this suggestion has no merit and does not remove the difficulty. The argument seems to be simply that a lawful line of separation of patent and application is found in the fact that the patent claims one use or application of the process and that the application claim is not limited in terms to that use. A mere statement of the argument seems to us to carry its own confutation. We never yet heard of a case in which a Court has been asked to find a line of division between two patents or claims, so that both patents may be declared valid, upon the argument that one calls for or specifies the only use or application of the invention that is set forth by the inventor while the claim of the other is distinguishable only from the first as a claim of invention in failing to state that use or application, thereby covering all uses including the one specified. In fact sufficient ground for the rejection of this argument is found in the repeated refusals of the Patent Office and the Courts to recognize the validity of two patents founded upon the same description and specification where one patent claims the invention generically and the other claims the same and no other invention specifically. Numerous cases on this proposition might be cited but even apart from that, it is self-evident that the inventions do not become different merely because the patentee recites in one the principal and practically the only proposed use of his invention, while in the other he claims his invention without particular reference to that principal and useful application of the same.

It is self-evident that in any event the present is not a case for

resort to the use of a disclaimer for the reason that the matter of the patent and application are inseparable as patentable matters and disclaimers are only permissible under the Statute and the patent law in cases where the matter disclaimed is a distinct and separable part of the matter claimed. A mere statement of function certainly cannot be disclaimed nor is it the office of a disclaimer to vary the words of a claim to make that which is generic specific, or to make that which is specific generic, nor can there be found any case, we believe, in which it has been held that a disclaimer may be resorted to for the purpose of eliminating from a claim the intended and only practical use of the invention set forth or proposed or suggested by the patentee in the manner found in the present case.

Applying the principle laid down in Miller vs. Mfg. Co., 151 U. S. 186, the Court held in Palmer Pneumatic Tire Co. vs. Lozier, 90 Fed. 732, C. C. A., 6th Circuit, that where the characteristic and essential element of a patented article is made the subject of a later patent, the last and not the first patent is void and this the Court held even though the invention of such element preceded that of the completed article. In the course of its decision the Court, interpreting Miller vs. Mfg. Co., distinctly said that in that case

> "The second patent was held void upon the ground that the matter of the invention was included in the matter of the invention for which the former patent was granted. That decision shows that it is not necessary to the rule that the patents should be for co-extensive inventions, or that the subject-matter thereof should be technically the same. The rule rests upon the broad and obvious ground that, if the second patent is for an invention that was necessary to the use of the invention first patented, it cannot be sustained."

It hardly needs further discussion to demonstrate that this principle applies exactly to the present case for as a matter of fact de Ferranti has suggested no way in which the invention of the patent which he has caused to be issued could be practiced without using the invention claimed in his application and, as a matter of fact, it is clear that the subject-matter forming the invention of the application is covered by the invention patented by the patent. In principle it is clear that there is no essential difference between the case in which the characteristic and essential element of the previously patented article is made the subject of a later patent and one in which a characteristic and essential element of a patented process is made or proposed to be made the subject of a later patent and this remains true where the process as claimed in the first patent contains supposedly limiting words limiting it to the principal and only disclosed application of the process as in the present case.

Indeed the suggestion that the difficulty in which de Ferranti has placed himself by taking the patent may be cured by a disclaimer to be hereafter filed or a reissue to be hereafter made, amounts practically to suggesting that the Commissioner now arrive at his de-

cision upon the question before him by treating the record before him as a moot record and that the interference from now on be conducted as a moot proceeding.

Having issued a patent to Ferranti, the Commissioner is without power to continue this interference because his authority under the law (Section 4904) is confined solely to determining the question of priority of invention as between an applicant and a patentee or between two pending applications, and assuming that the interference was properly declared in the beginning, the interference is now, owing to the issuance of the patent to de Ferranti for the same invention as that forming the subject of the application, one between two patents. Both parties to the interference now have a patent for the same invention. Under such circumstances the Section 4918 providing for a procedure by suit in equity whenever there are interfering patents, becomes the only section applicable to the case.

The power of the Commissioner to institute the interference arose solely under Section 4904 and solely because de Ferranti was presumably an applicant for the same invention as that for which Harmatta had obtained a patent and it was necessary under the Statute, for the Commissioner to determine the question of priority of invention in order to determine whether a second patent should be issued to de Ferranti for the same invention. A patent to de Ferranti having, however, been issued by the Commissioner, he is without authority to further continue this proceeding, since Section 4904 is the only section under which he is authorized to conduct interference proceedings.

There can be no question that the patent issued to de Ferranti is for the same invention as that for which he sought a patent by his original application and the existence of the patent now issued to him constitutes as complete a bar under the law to the issuance of the patent upon the application as now contained in the interference as if said issued patent were a prior patent to another inventor. Furthermore and beyond any question, the invention as claimed in the application is necessary to the practice of the invention covered by the claims in the patent issued and this fact creates the insuperable objection to the continuance of the proceeding and the issuance of any further patent to de Ferranti upon his application claims that said patent would prolong the monopoly secured to him by the patent already issued.

IN CONCLUSION, FERRANTI HAS BY HIS PATENT OBTAINED A MONOPOLY FOR A PROCESS APPLIED TO TURBINE MANUFACTURE INCLUDING THE PROCESS DISCLOSED BY FIGS. 1 AND 2 THEREOF; HE NOW ATTEMPTS TO COVER, IN THE APPLICATION, THE PROCESS OF FIGS. 1 AND 2 APPLIED BROADLY TO ANY APPLICATIONS OR USES OF IT AND THEREBY, IF SUCCESSFUL IN THIS ATTEMPT, HE WOULD BE EXTENDED THE LIFE OF THE MONOPOLY GRANTED BY THE PATENT ALREADY ISSUED.

The above facts are also directly in line with the case of American Bell Telephone Co. vs. National Telephone Co. et al., 109 Fed. Rep. 976, in which the Court held that

> "The Berliner patent, No. 463,569, claim 2, for a telephone transmitter, was anticipated by patent No. 233,969, to the same patentee, issued on a division of the same application, and which, in claim 4, covers a system consisting of the same transmitter in connection with a receiver, but in which such transmitter performs the same function as with any other receiver, and is applied to its appropriate and intended use; a receiver of some kind being essential to its operation."

It is respectfully submitted and urged that this interference should be dissolved upon the law and the facts disclosed above either by transmission of the same to the Law Examiner for decision on the motion to dissolve or by order of the Commissioner acting under his supervisory powers.

Respectfully,
TOWNSEND & DECKER,
Attorneys for Harmatta

IN THE MATTER OF THE INTERFERENCE OF

DE FERRANTI

vs.

HARMATTA

INTERFERENCE No. 36,709.

APPEAL ON MOTION.

Sir:

You are hereby informed that the decision of the Commissioner on the above appeal is as follows:

The office has no jurisdiction to try out a question of priority where one of the parties is a patentee unless the other party, if successful, is entitled to a patent; for a proceeding by an applicant who is not entitled to a patent conducted with the aim of establishing priority of invention over the patentee would be a mere attack upon

the validity of the patent which must be made if at all, in defense of a suit for infringement.

If it should be established that de Ferranti may not obtain a patent upon the present application because the subject-matter thereof is the same as that of his patent, he could perhaps cover the same matter by a reissue application, but an interference can be declared only after the reissue application has been filed.

As to Harmatta's delay in bringing the motion, the fact that his patent was held invalid in the district court in Massachusetts, and that the appeal heard last April was not decided until October is regarded as a sufficient excuse. Had the lower court been sustained, there would be nothing to fight about.

The decision of the examiner of interferences is sustained

THOMAS EWING,
Commissioner.

Hon. Commissioner of Patents,
Washington, D. C.
Sir:

IN THE MATTER OF THE INTERFERENCE OF

DE FERRANTI

vs.

HARMATTA

No. 36,709.

We have received a copy of the decision of the Commissioner of Patents dated December 3rd, 1915, on the appeal on Harmatta's

Motion to transmit a Motion to Dissolve. The whole text of this decision clearly seems to be that the Examiner of Interferences is reversed and in fact the attorneys so understood the Commissioner to state at the hearing, although the copy of the decision we have concludes with the expression:

"The decision of the Examiner of Interferences is sustained."

We think this is an obvious error and respectfully request information.

Very respectfully,

CFT/IL. TOWNSEND & DECKER.

THOMAS EWING,
Commissioner of Patents.

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

TO THE COMMISSIONER OF PATENTS.

Now comes the party De Ferranti by his Attorneys and petitions your Honor for a rehearing on the appeal of the party Harmatta from decision of the Primary Examiner refusing to transmit the motion to dissolve.

The grounds on which the rehearing is asked are as follows:

First, your Honor failed to take note of the fact that claims for substantially the same invention which forms the subject matter of the counts of the issue in the present interference, were twice made in the parent applicant, upon which patent No. 1,148,221 of De Ferranti was issued, and said claims were twice rejected by the Examiner and required to be cancelled as being for a separate invention from the other claims. Such claims were first made by amendment J[1] in amendment of December 8th, 1909 and again presented as claims 8, 9 and 10 of Paper No. 27, dated December 6th, 1910.

The Office having therefore placed itself on record as holding that the invention included in the counts of the present interference is for a different invention from that contained in the claims of the patent of De Ferranti, and this question being of no consequence in respect to priority of invention, said De Ferranti should not *at this stage of the proceedings* have placed upon him the burden of proving that the Office was right in its original holding.

The second ground is that the Harmatta patent, having been pending during the time when applicant was presenting claims for the invention included in the counts of the issue, in an application which afforded basis for such claims, the issue of the patent to Harmatta was clearly by inadvertence on the part of the Office and under the decisions, Harmatta is not entitled to derive any advantage from the mistake by the Patent Office. In Watson vs. Thomas, 106 O. G. 1776, it was held that where the patent was inadvertently granted "the two parties in the interference proceeding are to be treated as applicants with copending applications," citing Wurtz vs.

Harrington, 79 O. G. 337. See also Shaffer vs. Dolan, 108 O. G. 2146; Furman vs. Dean, 114 O. G. 1552; Paul vs. Hess, 115 O. G. 251; and Cutler vs. Leonard, 136 O. G. 438.

Third, it was believed your Honor, in considering the delay in bringing the motion, failed to consider the fact that the interference had progressed to a stage where De Ferranti had introduced all of his evidence which ineluctibly carried his date of invention back of Harmatta's date of filing.

Therefore, a rehearing of the matter and a reconsideration of your Honor's decision reversing the action of the Examiner of Interferences is respectfully requested.

Respectfully,
SPEAR, MIDDLETON, DONALDSON & SPEAR,
Attorneys for de Ferranti.

UNITED STATES PATENT OFFICE,

BEFORE THE LAW EXAMINER.

In re Interference:

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

BRIEF FOR HARMATTA.

This interference now comes before your Honor for decision on the merits of a motion to dissolve brought by Harmatta and duly

transmitted to your Honor after appeal to the Honorable Commissioner of Patents in person.

Harmatta, the senior party to the interference, is a patentee, and de Ferranti, the junior party, is an applicant, he having copied certain broad claims from the Harmatta patent No. 1,046,066 involved in this interference for the purpose of contesting priority thereof with Harmatta. Harmatta's patent involved in this interference was issued on December 3rd 1912 on an application filed December 3rd 1903. De Ferranti's application involved in this interference was not filed until December 29th 1911 as an alleged division of an earlier application of his filed May 14th 1904. The claims of the interference are for a process of electric welding now known broadly as "spot welding." On July 27 1915 de Ferranti, the junior party to this interference, had issued to him a United States patent No. 1,148,221 for Process for Electrically Welding Turbine Blades, this being the patent issued on the original application of which Ferranti's application directly involved in this interference is alleged to be a division. Figures 1 and 2 of this patent are the same as the figures of the Ferranti application in the interference. The claims of the patent are for a process or method based on the disclosures of Figures 1 and 2 which are also the subject of the pending application.

The substance of the motion now brought by Harmatta to dissolve the interference is that the issuing of a patent to de Ferranti for the invention claimed in his application declared to be in interference with Harmatta would effect a double patenting of the invention already patented to de Ferranti by his Letters Patent No. 1,148,221.

In his issued patent No. 1,148,221 Ferranti describes and claims a certain method of electrically welding turbine blades to their carrying element. In his application involved in this interference he claims the method of electric welding which is based on the same identical process as that claimed in the patent, the wording of the claims of the application, however, being different than the wording of the claims of the patent although both are drawn to processes. The claims of the application are broader in scope than those of the patent and if granted in a patent to Ferranti with a construction broad enough to cover the process he discloses, would be to grant to Ferranti an extension of the monopoly previously granted to him by his issued patent No. 1,148,221.

The contention is absolutely correct that in his patent No. 1,148,221 referred to in the motion, Ferranti claims his same substantial method or process that he claims in his application in interference and that there is no difference in the two methods to be inferred merely because in the patent he defines the process by reference to the result of welding onto the projections. In other words, in the application in interference the invention claimed is a method or process of welding done by welding to projections while in the patent the method or process is identified by the necessary physical ac-

tion which takes place in the operation of welding to the projections.

IN REACHING A SATISFACTORY CONCLUSION IN THIS MATTER IT MUST BE BORNE IN MIND THAT THE DRAWINGS AND SPECIFICATIONS OF THE APPLICATION AND PATENT ARE EXACTLY ALIKE; THAT THE ONE DESCRIBES NO OTHER DIFFERENT OPERATION THAN THAT DESCRIBED AND SET FORTH IN THE OTHER; THAT THE TWO ARE BASED UPON THE SAME IDENTICAL ORIGINAL APPLICATION; THAT THEY DO NOT BEAR THE RELATION TO ONE ANOTHER OF INVENTION AND IMPROVEMENT; THAT THE CLAIMS, THOUGH IN DIFFERENT WORDS, REFER TO EXACTLY THE SAME PRACTICAL OPERATION AND ARE FOUNDED UPON THE INVENTION AS DISCLOSED IN THE ORIGINAL APPLICATION AND THAT THE PATENT CLAIM DIFFERS FROM THE APPLICATION CLAIM ONLY IN DESCRIBING A FUNCTION OF THE OPERATION OMITTED FROM THE APPLICATION CLAIM. Assuming that it were true, which does not appear to be the case, that one might perhaps modify the operation as claimed in the application so that the normal equalization of the heat capacity would not take place, it nevertheless remains true that no such suggestion or modification of operation is in any manner suggested in either specification or in the drawings of either case. In other words, *the process or operation patented by the patent is the same as that which the applicant seeks to patent by the application.*

INVENTIONS OF PATENT AND APPLICATION INSEPARABLE.

It seems to us clear that the matter sought to be covered by the patent is inseparably involved in the matter sought to be covered by the application; that the patent and application are in fact for the same substantial invention and that the circumstances of this case are exactly parallel to the leading cases of Thompson-Houston Electric Co. vs. Housic Railway Co., 82 Fed. 461, Circuit Court of Appeals, 2nd Circuit, Thomson-Houston Electric Co. vs. Jeffrey Mg. Co., 101 Fed. 121, C. C. A., 6th Circuit, which have been followed in numerous other cases and which were founded upon decisions of the Supreme Court of the United States rendered on substantially the same state of facts in the case of Miller vs. Eagle Co., 151 U. S. 186. We also cite:

Plummer vs. Sargent, 120 U. S. 442;
Lock Co. vs. Mosler, 127 U. S. 354;
McClain vs. Ortmeyer, 141 U. S. 419;
Palmer Pneumatic Tire Co. vs. Lozier, 90 Fed. Rep. 732;
Thomson-Houston Co. vs. Black River Co., 124 Fed. Rep. 501;
Malby Electric vs. Thomson-Houston, 148 Fed. Rep. 845;
Thomson-Houston vs. Western Electric, 158 Fed. Rep 813.

Under the authority of these cases the Patent Office is confronted *with the condition that de Ferranti has now obtained a patent for the actual invention for which he is seeking a patent by the application in interference and that said patent must stand as an effectual bar to the grant of a patent upon the application.* In principle the circumstances and conditions now confronting the Patent Office of the state of facts arising from the act of the applicant in taking the patent are in no wise different than they would be if it should be discovered that the invention had been patented to some other person or even to the applicant himself by a previous patent granted prior to any date of invention appearing in this record either by the application on record or by allegation of the preliminary statement and that both parties now having obtained a patent it is the plain duty of the Patent Office to terminate this interference, leaving the party Ferranti to take such step or steps as he may be advised are necessary in order to protect his rights.

Some suggestion has been made that the objection that the invention covered by the patent and that covered by the application are inseparably involved may be avoided on some theory that the patent is for a method of attaching turbine blades and that in the application claim no reference is made to attaching turbine blades. In our view this suggestion has no merit and does not remove the difficulty. The argument seems to be simply that a lawful line of separation of patent and application is found in the fact that the patent claims one use or application of the process and that the application claim is not limited in terms to that use. A mere statement of the argument seems to us to carry its own confutation. We never yet heard of a case in which a Court has been asked to find a line of division between two patents or claims, so that both patents may be declared valid, upon the argument that one calls for or specifies the only use or application of the invention that is set forth by the inventor while the claim of the other is distinguishable only from the first as a claim of invention in failing to state that use or application, thereby covering all uses including the one specified. In fact sufficient ground for the rejection of this argument is found in the repeated refusals of the Patent Office and the Courts to recognize the validity of two patents founded upon the same description and specification where one patent claims the invention generically and the other claims the same and no other invention specifically. Numerous cases on this proposition might be cited but even apart from that, it is self-evident that the inventions do not become different merely because the patentee recites in one the principal and practically the only proposed use of his invention, while in the other he claims his invention without particular reference to that principal and useful application of the same.

Applying the principle laid down in Miller vs. Eagle Co., 151 U. S. 186, the Court held in Palmer Pneumatic Tire Co. vs. Lozier, 90 Fed. 732, C. C. A., 6th Circuit, that where the characteristic and essential element of a patented article is made the subject of a later patent, the last and not the first patent is void and this the Court

held even though the invention of such element preceded that of the completed article. In the course of its decision the Court, interpreting Miller vs. Eagle Co., distinctly said that in that case

> "The second patent was held void upon the ground that the matter of the invention was included in the matter of the invention for which the former patent was granted. That decision shows that it is not necessary to the rule that the patents should be for co-extensive inventions, or that the subject-matter thereof should be technically the same. The rule rests upon the broad and obvious ground that, if the second patent is for an invention that was necessary to the use of the invention first patented, it cannot be sustained."

It hardly needs further discussion to demonstrate that this principle applies exactly to the present case, for as a matter of fact de Ferranti has suggested no way in which the invention of the patent which he has caused to be issued could be practiced without using the invention claimed in his application and, as a matter of fact, it is clear that the subject-matter forming the invention of the application is covered by the invention patented by the patent. In principle it is clear that there is no essential difference between the case in which the characteristic and essential element of the previously patented article is made the subject of a later patent and one in which a characteristic and essential element of a patented process is made or proposed to be made the subject of a later patent and this remains true where the process as claimed in the first patent contains supposedly limiting words limiting it to the principal and only disclosed application of the process as in the present case.

The state of facts existing in Ferranti's patent and application leads to the query: HOW CAN TWO *DIFFERENT* INVENTIONS BE PREDICATED UPON OR EVEN INCLUDE THE SAME PROCESS? The mere addition to the claim of unpatentable features or features old in the art or features necessary to the carrying out of the process does not make it a different invention.

THE PROCESS OF FIGS. 1 AND 2 OF THE PATENT, IT MUST BE ADMITTED, IS COVERED BY THE CLAIMS IN THE PATENT; therefore the process claims of the application must necessarily be for the same invention, they being predicated on the process disclosed by Figs. 1 and 2 even though they may be expressed in a different guise and in some cases with the addition of unpatentable features.

As was held in Ex parte Woodward, 1890 C. D. 169, separate patents cannot be allowed for the same invention under different guises or as different mental figments.

Applications are not severable excepting upon structural (that is, physical) lines which actually divide the machine (process) into separable parts. By taking out a patent for the device arranged to operate in a specific manner the applicant abandoned to the public

the more general claims which might have been predicated upon the same combination of parts. See Fassett vs. Ewart Mfg. Co., 58 Fed. 360.

The claims of the Ferranti application are based upon the same original application as the patent and are predicated on the same inventive act. The case is not that of an application for a broad invention followed by an application for a subsequently invented improvement and therefore to issue a patent to Ferranti on his present application would result in double patenting following the ruling laid down in Otis Elevator Co. vs. Portland Co., 127 Fed. 557. See also on this point Morse Chain Co. vs. Link Belt Co., 164 Fed. 331.

Having issued a patent to Ferranti, the Commissioner is without power to continue this interference because his authority under the law (Section 4904) is confined solely to determining the question of priority of invention as between an applicant and a patentee or between two pending applications, and assuming that the interference was properly declared in the beginning, the interference is now, owing to the issuance of the patent to de Ferranti for the same invention as that forming the subject of the application, one between two patents. Both parties to the interference now have a patent for the same invention. Under such circumstances the Section 4918 providing for a procedure by suit in equity whenever there are interfering patents, becomes the only section applicable to the case.

The power of the Commissioner to institute the interference arose solely under Section 4904 and solely because de Ferranti was presumably an applicant for the same invention as that for which Harmatta had obtained a patent and it was necessary, under the Statute, for the Commissioner to determine the question of priority of invention in order to determine whether a second patent should be issued to de Ferranti for the same invention. A patent to de Ferranti having, however, been issued by the Commissioner, he is without authority to further continue this proceeding, since Section 4904 is the only section under which he is authorized to conduct interference proceedings.

THE SUBJECT-MATTER OF THE APPLICATION (THE PROCESS OF FIGS. 1 AND 2) IS COMPLETELY EMBODIED IN THE CLAIMS OF THE PATENT.

There can be no question that the patent issued to de Ferranti is for the same invention as that for which he sought a patent by his original application and the existence of the patent now issued to him constitutes as complete a bar under the law to the issuance of the patent upon the application as now contained in the interference as if said issued patent were a prior patent to another inventor. Furthermore and beyond any question, the invention as claimed in the application is necessary to the practice of the invention covered by the claims in the patent issued and this fact creates the insuperable objection to the continuance of the proceeding and the issuance of any further patent to de Ferranti upon his applica-

tion claims that said patent would prolong the monopoly secured to him by the patent already issued.

The above facts are also directly in line with the case of American Bell Telephone Co. vs. National Telephone Co., et al., 109 Fed. Rep. 976, in which the Court held that

> "The Berliner patent, No. 463,569, claim 2, for a telephone transmitter, was anticipated by patent No. 233,969, to the same patentee, issued on a division of the same application, and which, in claim 4, covers a system consisting of the same transmitter in connection with a receiver, but in which such transmitter performs the same function as with any other receiver, and is applied to its appropriate and intended use; a receiver of some kind being essential to its operation."

SPECIFIC AND BROAD CLAIMS.

In his patent Ferranti has specified claims to the process as used for a specific purpose, while in the application the claims are broad to the process for any uses.

Where a patent has been issued for specific devices, a second patent with generic claims covering the specific devices would be void for double patenting. Gold vs. Gold, 187 Fed. 273.

A patent with specific narrow claims followed by a second patent with claims of broad or generic scope based on an improvement is double patenting. Union Typewriter vs. Smith & Bros., 173 Fed. 288.

Two patents may be for the same invention although the earlier claims only a specific machine and the later claims broadly a genus which includes the earlier specific machine and others as well. Otis Elevator Co. vs. Portland Co., 127 Fed. 557.

There is no line of division based merely on scope or breadth of claim. Porter vs. Louden, 73 O. G. 1551 (Court of Appeals of the District of Columbia).

No lawful decision based upon a mere distinction of scope of claims based upon the same subject-matter or entity. Ex parte Holt, 1884 C. D. 43 is a clear statement of the case. See also Ex parte Mullen, 1890 C. D. 9 in which the cases in which division is permissible are clearly expounded. Also, Ex parte Neiswanger, 1890 C. D. 37.

RULE 106.

> "When a part only of an application is involved in an interference, the applicant may withdraw from his application the subject-matter adjudged not to interfere, and file a new application therefor, or he may file a divisional application for the subject-matter involved, if the invention can be legitimately divided: PROVIDED, That no claim shall be made in either application broad enough to include matter claimed in the other."

Clearly Ferranti's position is in violation of the provisions of this rule of the Patent Office in that the claims of both his patent and his application are broad enough to cover the process claimed in both cases and this must necessarily be so as the claims of both cases are drawn to cover the same identical process of welding.

IN ORDER TO RECEIVE TWO PATENTS FERRANTI MUST HAVE TWO INVENTIONS AND HOW CAN HE HAVE TWO INVENTIONS WHEN HE HAS INVENTED ONLY ONE PROCESS?

REISSUE AND DISCLAIMER.

As it has been argued that the difficulty of double patenting might be cleared up by either of the above remedies, to wit,—reissue or disclaimer, it might be well to briefly allude to them although they are entirely aside from the merits of the motion. The question of reissue has been disposed of by the Commissioner in his decision dated December 3rd, 1915. This ruling of the Commissioner applies equally as well to a proposed disclaimer. What kind of a disclaimer would be applicable to these circumstances and whether or not the case is one for disclaimer under the law, or whether in fact a disclaimer in one of two patents conflicting in being for the same invention would operate to make the other valid, and whether or not any actual disclaimer has been filed or will be filed, are matters upon which the Patent Office is not called upon to pass at this stage of the case or under the status of the record as now presented. What the applicant may choose to do lies wholly within his own mind and is subject wholly to future action on his behalf.

It is self-evident that in any event the present is not a case for resort to the use of a disclaimer for the reason that the matter of the patent and application are inseparable as patentable matters and disclaimers are only permissible under the Statute and the patent law in cases where the matter disclaimed is a distinct and separable part of the matter claimed. A mere statement of function certainly cannot be disclaimed nor is it the office of a disclaimer to vary the words of a claim to make that which is generic specific, or to make that which is specific generic, nor can there be found any case, we believe, in which it has been held that a disclaimer may be resorted to for the purpose of eliminating from a claim the intended and only practical use of the invention set forth or proposed or suggested by the patentee in the manner found in the present case.

IN CONCLUSION, FERRANTI HAS BY HIS PATENT OBTAINED A MONOPOLY FOR A PROCESS APPLIED TO TURBINE MANUFACTURE INCLUDING THE PROCESS DISCLOSED BY FIGS. 1 AND 2 THEREOF; HE NOW AT-

TEMPTS TO COVER, IN THE APPLICATION, THE PROCESS OF FIGS. 1 AND 2 APPLIED BROADLY TO ANY APPLICATIONS OR USES OF IT AND THEREBY, IF SUCCESSFUL IN THIS ATTEMPT, HE WOULD BE EXTENDING THE LIFE OF THE MONOPOLY GRANTED BY THE PATENT ALREADY ISSUED AND WOULD BE RECEIVING TWO PATENTS FOR THE SAME INVENTION.

It is respectfully submitted and urged that this interference should be dissolved upon the law and the facts disclosed above.

Respectfully,

TOWNSEND & DECKER,
Attorneys for Harmatta.

New York, January 4th 1916.

36,709—50
MCV

Hearing:
Jan. 5, 1916.

IN THE UNITED STATES PATENT OFFICE.

PATENT INTERFERENCE No. 36,709.

DE FERRANTI

vs.

HARMATTA.

MOTION FOR DISSOLUTION.

ELECTRIC WELDING.

Application of Sebastian Ziani de Ferranti filed Dec. 29, 1911, Ser. No. 668,464, division of application No. 208,034, filed May 14, 1904.

Patent granted Johann Harmatta Dec. 3, 1912, No. 1,046,066, on application filed Dec. 3, 1903, No. 183,677.

Messrs. Spear, Middleton, Donaldson & Spear for de Ferranti.
Messrs. Townsend & Decker for Harmatta.

The party Harmatta moves for a dissolution of the interference on the ground that the grant to the party de Ferranti on July 27, 1915, of patent No. 1,148,221 for Process of Electrically Welding Turbine Blades constitutes a bar to the grant to de Ferranti of a patent containing the claims which constitute the issue of this interference. In other words, it is contended by Harmatta that if a patent were granted to de Ferranti containing the claims of the interference issue is would be double patenting of the invention covered by de Ferranti's patent No. 1,148,221.

The interference issue is:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce as isolated spot or spots of union, leaving distinct or well defined areas in which the pieces are not welded together.

The claims of the de Ferranti patent are:

1. The method of attaching turbine blades to their carrier of relatively great mass which consists in adjusting the heat capacity of the localized area of the carrier at the point of attachment by partially isolating these areas from the remainder of the carrier so that a welding temperature may be reached notwithstanding the cooling effect of the mass of the carrier, and passing a uniform electric heating current directly through the carrier and by way of the clamps through the blades to weld the blades in succession to the carrier, substantially as described.

2. The method of attaching turbine blades to their rotor carrying elements one by one, consisting in equalizing the heat capacity of the welding parts by limiting the conducting areas of the carrier at the points of blade attachment symmetrically in relation to the axis of rotation of the rotor, and inclosing the blades between clamps so that on heating locally by a uniform electric current, the blades and carrier rise to approximately the same temperature on welding the blades to the carrier so prepared, substantially as described.

3. Process for the attachment of turbine blades to their carriers consisting in partially isolating those portions of the carrier in the neighborhood of the points of attachment of the blades, to limit

the cross-sectional area available for the conduction of heat therefrom; artificially increasing the volume of the blades by contacting them with metal masses of high heat conductive capacity and finally welding together the carriers and blades so prepared.

4. Process for the attachment of turbine blades to their carriers, consisting in forming circumferential grooves with intervening rings of metal around the carrier thereby limiting the cross sectional area available for the conduction of heat from the point of attachment so that on heating locally, said blade and said carrier rise to approximately the same temperature and welding each blade to a plurality of said rings, as set forth.

5. The method herein described of constructing a turbine wheel, ring or drum, the same consisting first in forming said wheel symmetrically in relation to its center of rotation with the parts next to the welding points reduced to properly conform to the volume of the blades and electrically welding said blades at the said points whereby the symmetry of the wheel is maintained.

The invention forming the bases of this interference is a process of electric welding, the characteristic feature of which is the welding together of two pieces of metal at spots only of the contacting surfaces by heat and pressure localized at the spots at which the welding is to take place. There is no limitation in any of the counts as to the instrumentalities employed in carrying out the process, neither is there any limitation in the counts as to the character of the pieces of metal to be welded together. In the drawing of the de Ferranti application involved in interference there are two figures, Figure 1 being described as showing a turbine bladed element, having the blades welded thereto and Figure 2 as a part side elevation of the bladed element shown in Figure 1. There is no disclosure in either of the figures of the means for producing pressure or of the means for electrically heating the pieces of metal to be electrically spot welded together. The specification of the de Ferranti application is equally silent as to the specific steps or means employed in subjecting the parts to be welded together to heat and pressure. After describing the manner in which a series of projections are formed on the surface of the wheel to which the blades are to be welded, the specification of the application proceeds to state:

> The blade *d*, is welded to certain of the projections, *f*, by passing across the points of contact of the opposing surfaces, an electric current in a known manner.

The application involved in interference is a division of the de Ferranti application which matured into patent No. 1,148,221. The drawing of the patent contains seventeen figures including the figures of the application drawing. The drawing of the patent illustrates various modifications directed to securing proper welding temperatures of the turbine wheel and blades and also shows an

apparatus by which the steps of the process claimed may be carried out.

The claims of the de Ferranti patent each contain limitations which are not readable upon either drawing or specification of the de Ferranti application. Thus claim 1 calls for "passing a uniform electric heating current directly through the carrier and by way of the clamps through the blades to weld the blades in succession to the carrier." There is no disclosure whatever in the de Ferranti application of clamps for the blades to be welded to the carreir.

Claim 2 of the patent specifies, "enclosing the blades between clamps so that on heating locally by a uniform electric current, the blades and carrier rise to approximately the same temperature on welding the blades to the carrier so prepared." What was said with respect to the use of clamps in connection with claim 1 also applies to claim 2.

Claim 3 states, "artificially increasing the volume of the blades by contacting them with metal masses of high heat conductive capacity." This refers to the special character of the clamps and is described in lines 38 to 42, inclusive, page 2 of the printed specification. As has heretofore been stated, there are no clamps of any kind disclosed in the application involved in interference.

Claim 4 of the patent is limited to a special form of carrier to which the turbine blades are to be attached, i. e., one having circumferential grooves with intervening rings of metal. No such carrier is disclosed in the de Ferranti application.

Claim 5 of the patent calls for a method of constructing a turbine wheel which includes among other things, "forming the wheel symmetrically in relation to its center of rotation * * * whereby the symmetry of the wheel is maintained." There is no disclosure in the de Ferranti application of any step such as that noted with respect to claim 5.

It seems clear to the law examiner that not only are the claims of the de Ferranti patent limited to matter not disclosed in the application but the claims of the application involved in interference recite methods which can be carried out without employing the steps of the method claims of the patent. This is evidenced not only by the disclosure of the de Ferranti application but by the disclosure of the Harmatta patent which fails to respond to the limitations in the de Ferranti patent claims to which reference has been made above.

The brief filed by Harmatta does not discuss the specific limitations in the claims of the de Ferranti patent to which reference has been made herein but states generally that the inclusion of unpatentable limitations in the claims of a patent will not avoid the bar of double patenting. It need only be said on this point that nothing has been presented here to show that the limitations in the claims of the patent, to which reference has been made, are immaterial or unpatentable, even if the law examiner had authority to pass on that question.

Considerable weight is attached by the moving party in his brief to the fact that Figures 1 and 2 of the de Ferranti patent correspond to the Figures of the application drawing. The figures in question, taken either alone or in connection with the description of the figures in application or patent, do not support the language or the substance of the claims of the patent.

It does not appear to be material to the question of double patenting that the claims involved in interference are broader than the claims of the de Ferranti patent and that such broader claims are contained in a later filed divisional application. Welsbach Light Co. v. Cohn, Fed. Rep. 181, 123.

The motion for dissolution is denied.

DE FERRANTI

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

THOMAS EWING,
Commissioner of Patents.

6—1652

The law examiner having denied Harmatta's motion for dissolution filed October 28, 1915, proceedings herein are resumed, and the times for taking testimony and for final hearing are reset as follows:

Testimony in chief of De Ferranti to close March 22, 1916.
Testimony of Harmatta to close April 22, 1916.
Rebuttal testimony of De Ferranti to close May 8, 1916.
Final hearing: July 11, 1916, at 11 A. M.

H. E. STAUFFER,
Examiner of Interferences.

U. S. Patent Office.

Intf. No. 36709, Paper No. 54.

UNITED STATES PATENT OFFICE.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

PETITION TO THE HONORABLE COMMISSIONER OF PATENTS IN PERSON.

Now comes Johann Harmatta, by his attorneys, and respectfully petitions your Honor to exercise your supervisory powers and review the decision of the Law Examiner rendered January 19th 1916, denying your petitioner's motion for dissolution of this interference. The motion for dissolution, in brief, is that de Ferranti has no right to make the interference claims for the reason that to issue such claims to him in his application involved in the interference would be double patenting of the invention covered by de Ferranti's prior patent No. 1,148,221.

It is contended that the Law Examiner is clearly in error in his conclusion as to what constitutes double patenting under the law as laid down in the numerous authorities cited by your petitioner in his brief already filed.

The Law Examiner has not finally determined the question by his decision for the reason that the decision turns on the point that he has no information that the limitations in the claims of the patent are immaterial or unpatentable. This was discussed and urged in the oral argument and the Law Examiner should take judicial notice of knowledge which is in the possession of the Examiners of the Patent Office; in other words we ask for a review of the Law Examiner's decision upon the ground that in refusing to take note of the state of the art in respect to elementary details of processes of electric welding as known to the officials of the Patent Office and as urged orally at the hearing, his decision is not and cannot be fully decisive of the question raised by Harmatta's motion.

Further, the Law Examiner by his decision has completely overlooked the provisions of Rule 106 which was raised in your petitioner's brief.

tive decision as to the right of a party to make the claims or as to the patentability of claims. I do not find that the circumstances of this case justify the exercise of my supervisory authority to review the decision of the law examiner.

The petition is denied.

THOMAS EWING,
Commissioner.

January 28, 1916.

By direction of the Commissioner:

Very respectfully,

W. F. WOOLARD,
Chief Clerk.

F.

S. Z. de Ferranti,
c/o Spear, Middleton, Donaldson & Spear,
Washington, D. C.
Johann Harmatta,
c/o Townsend & Decker,
149 Broadway,
New York City.

Docket Clerk. 36,709—57.
Apr. 15, 1916.
U. S. Patent Office. Testimony for

UNITED STATES PATENT OFFICE.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

(batch 1)

HARMATTA.

New York, N. Y., March 20th, 1916.

Messrs. Spear, Middleton, Donaldson & Spear,
Victor Building,
Washington, D. C.

GENTLEMEN:

PLEASE TAKE NOTICE that on Tuesday, March 28th, 1916, beginning at 11 a. m., at the office of Townsend & Decker, 149

Broadway, New York, before George E. Brown, Notary Public in and for the County of New York or some other duly authorized officer, the party Harmatta will proceed to take the depositions of the following witnesses in his belief in the above interference:

Hermann Lemp of Erie, Pa.;
James H. Gravell of Philadelphia, Pa.;

and possibly others. The examination will continue from time to time until completed and you are invited to attend and cross-examine.

TOWNSEND & DECKER,
Attorneys for Harmatta.

Due service of the above notice admitted this 22" day of March 1916.

SPEAR, MIDDLETON, DONALDSON & SPEAR,
Attorneys for De Ferranti.

UNITED STATES PATENT OFFICE.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

New York, N. Y., March 28th, 1916.

Testimony taken on behalf of Harmatta pursuant to the annexed notice at the office of Townsend & Decker, 149 Broadway, beginning at 11 A. M., March 28, 1916.

Present: MR. H. C. TOWNSEND for Harmatta.
MR. WILLIAM F. HALL for de Ferranti.

HERMANN LEMP, being duly sworn, deposes and says as follows in answers to interrogations by MR. TOWNSEND:

Question 1. What is your name, age, residence and occupation?

Answer. Hermann Lemp, 53, Engineer of the Erie Works General Electric Company, Erie, Pa.

Q. 2. Have you had any practical knowledge and experience in the art of electric welding?

A. Yes, I was chief engineer of the Thomson Electric Welding Company for seven years.

Q. 3. Will you please state fully the nature and extent of your knowledge and experience in the art?

A. From 1888 until 1895 I was in full charge of the Commercial development of electric welding apparatus and accessories for the utilization of the Thomson Electric Welding process and therefore thoroughly acquainted with the early history and practices followed in the art of welding and the means employed for applying them in the art.

Q. 4. Since the date last mentioned have you kept yourself informed in a general way as to the progress of that art?

A. I naturally have in a general way but my time having been fully occupied with my own work, I have not followed it in detail.

Q. 5. I call your attention to a copy of the provisional specification of de Ferranti filed in connection with proceedings for obtaining the British patent No. 11921 of 1903 unaccompanied by drawings, a certified copy of which provisional specification is on file in the United States Patent Office as a part of a stipulation entered into between the parties in this interference on or about the 14th day of May 1915 and acknowledged by the Office Letter dated May 18th 1915 and will ask you whether you have read and considered the description forming that provisional specification wholly apart from the complete specification and any drawings accompanying the latter, and whether you believe that you understand that description in the provisional specification so far as it goes?

A. Yes, I have.

Q. 6. Will you please state from the standpoint of one having a practical knowledge and experience of the art of electric welding as it existed at the date of filing of that provisional description in the British Patent Office, to wit: May 25th 1903, your understanding of the invention purporting to be described in that specification and as desclosed thereby alone and apart from the complete specification and any drawings accompanying the latter?

(By Mr. Hall: Objected to as incompetent and inadmissible as an effort to adduce expert testimony regarding the disclosure in the provisional specification without leave of the Examiner of Interferences.)

A. The provisional specification describes to me a method of shaping or modifying the surface of a mass greater than that to which a smaller mass is to be welded in such a way as to produce equal heating of the two parts to be welded and which method is so entirely the usual one followed by us in everyday welding operations, as thoroughly explained in the literature of the early days of the art, that it does not disclose to me anything novel. It is merely the application of wellknown principles to a specific case numbers of which have been brought to our attention times and times again and were met in similar matters as described in the provisional specification of de Ferranti. When two pieces of metal had to be welded together by the Thomson process one of which was of a larger

section than the other, the usual procedure was and still is to decrease the section of the larger piece at the point where it was to be welded to the smaller piece either by cutting away part of the metal or by forging or forming projecting tits of a section as near as possible to the smaller part to be welded thereto. Sometimes these projections were cast on, in other cases they were produced by removing metal just as the special condition of the work would demand it. This method of procedure was always necessary for the purpose of creating an equal production of heat on both parts to be welded by making the resistance of the metal through which the heating current flows as nearly as possible alike and conversely of preventing the carrying off of heat from the abutments to be welded in as equal a manner as possible.

(By Mr. Hall: In addition to the objection made to the question all of the answer commencing with the words "and which method," line 5, is objected to as stating a mere conclusion, as secondary evidence and as irrelevant, immaterial and inadmissible in respect to the practice followed in the Thomson process since it endeavors to introduce a question of the practice which has been followed in the art. This is immaterial to the issues in this case, and cannot be introduced in this manner or without special leave of the Examiner of Interferences or Commissioner of Patents.)

Q. 7. Will you please mention some of the early literature that you have in mind as referring to the shaping or modifying the surface, as mentioned by you, and compare what is set out in the instances you may refer to with what you understand to be the manners of shaping or modifying the surface to which de Ferranti refers in the provisional description?

(By Mr. Hall: The objections made to the last answer and question are repeated. The question is also objected to as calling for incompetent and inadmissible evidence since it seeks to bring into the case the prior art.)

A. I refer to the original Thomson patent No. 347,141 in which, in Fig. 8, it is shown how the blade of a knife is chamfered to meet the diameter of the handle. Again, to one of the earliest publications by Prof. Elihu Thomson on the art of electric welding, as given in the Electrical World of December 25th 1886. I refer with particular attention to paragraph on page 399 which I herewith quote:

"When the pieces are of the same metal and of the same size or section, the junction is made by placing the ends of the pieces abutted midway between the clamps before applying the pressure to force them together and the current to weld them

But when they are of different metals or of different sections, the abutment or meeting point is placed nearer the clamp carrying the most resisting metal; or, the piece of smaller section, or the metal most readily fused, as the case may be, is so placed so as to project least, for the purpose of favoring the accumulation of heat in the other piece.

"In joining pieces of different diameters the end of the large piece is reduced to the size of the smaller before attempting to effect the weld."

I also refer to patent 396,010 of Jan. 8th 1889, Fig. 9, described on second page 2:

"This knob or protuberance may be utilized in a variety of ways—as, for example, a lateral bar may be welded to the knob by my electric-welding process, which forms the subject of prior application; or, the lateral projections b, Fig. 10, having been formed at a distance from the end of a bar, the end may be bent to shape, as shown in Fig. 11, and finally welded electrically as a ring, as shown in Fig. 12, thus forming a loop on the end of the bar."

Also to patent No. 434,530, of August 19th, 1890, Fig. 10; and patent 487,302, December 6th, 1892, Fig. 4, described on second page lines 90 to 110. Also to article in the "Iron Age" of January 28th, 1892, particularly referring to Figs. 23, 25, on page 151; Figs. 52, 56 and 57 on page 153; and Figs. 76 and 78 on page 155.

In the various references made in all cases it is pointed out that the sections of the parts to be welded electrically together should be modified so as to be as nearly equal as possible to produce equal heating. Sometimes only two welding surfaces are brought together; at other times there are at the same time four welding surfaces brought together or more. In most cases the larger surfaces are reduced in size to the smaller by forging methods. In the case of Fig. 76 metal is removed and in Fig. 95, page 157 of the "Iron Age" article, the parts to be welded are cast in a mold to give the proper section.

In this Ferranti specification there is stated that

"In carrying out my invention according to one modification grooves may be cut across the edge of the ring"

and again, at another place, it is stated:

"Again, the ring may be built up of a set of thin laminae, the edges of which are notched, the laminae being assembled in such a way that the notches are 'stepped' with regard to each other, the intervening projections of metal thus following the shape of the turbine blades to be welded to them."

In the first of these modifications a machine formed surface is produced substantially of the section of the turbine blade to be welded thereto; in the second cited modification a similar section is produced from built-up laminated disks both of which are in substance like the weld produced in Fig. 9, patent 396,010 cited before, the difference being that in the patent the tits are forged and raised from the surface while in the Ferranti description the tits are produced by cutting away the solid metal.

In Fig. 76, page 155, "Iron Age" article, the bottom piece of a projectile is hollowed out and its circular section made to conform to that of the central body for the purpose of equalizing the heat at the weld.

The references given all clearly establish the fact that it was well understood that in order to electrically weld surfaces of unequal section together and produce a strong weld, the surfaces had to be shaped either by cutting away or by adding projections to bring about as near as possible equal heat at the point of weld.

(Attorney for Harmatta gives notice that he will refer at the final hearing to the publications and patents mentioned by the witness and as found in the records of the Patent Office.)

Q. 8. Referring to the statement of the description that according to one modification grooves may be cut across the edge of the ring, to what extent would the surface of the blade be welded to the carrier by following the procedure there referred to of modifying th surface as you understand it and in view of the statement of the inventor that the object to be kept in mind in the various modifications is to enable the temperature to rise to the welding point while at the same time leaving sufficient areas untouched to insure mechanical strength in the welding joint?

A. The object in any weld is to have as large a welded surface as possible to insure a strong mechanical joint. The inventor had evidently this featutre in mind; and considers that modification the best which would insure a weld extending over the whole surface of the turbine blade. In both of the modifications cited by me and particularly the one referred to in this question, a solid weld including the whole area of the blade would be produced.

Q. 9. Referring to the statement of the specification

"Again intersecting sets of grooves inclined to one another may be cut on the edge of the ring."

what does the description disclose to you as one skilled in the art at date of the filing of the provisional and speaking from the standpoint of your knowledge of the art of electric welding as to the width and number of the intersecting grooves?

(By Mr. Hall: Objection following Q. 6 is repeated.)

A. It would tell me that in order to secure the strongest weld the grooves cut into the surface of the ring would be made as narrow and as deep as possible to produce the proper heat and to maintain the continuity of the weld over as large a surface as possible.

Adjourned to 2 p. m.

Examination Continued:

Q. 10. Might or might not the weld resulting from the modification of the metal of the carrier in the manner referred to in your last answer involve practically the whole surface of the blade presented to the carrier?

(By Mr. Hall: Same objection.)

A. Yes, it might and the more it does the nearer it will comply with the conditions laid down by de Farranti to insure the greatest mechanical strength at the welded joint. The method of welding the blades on to the carrier is of course nothing more than the well known butt welding process known as the Thomson process in which the parts to be united, when brought to the welding heat, are pressed together and from this result an expansion of metal at the weld usually known as the burr which, in the particular modification described by Ferranti, would, in the final part of the operation, close up the gaps made by the slots or grooves and produce substantially one uniform welded surface between the carrier and the blade.

Direct examination closed.

Cross-examination without waiving objections made on the direct:

X-Q. 1. Is the Thomson Electric Welding Company a branch of or controlled by the General Electric Company?

A. If it is, it is news to me. I never heard such to be the case.

X-Q. 2. Where is the main office of the Thomson Electric Welding Company?

A. Lynn, Mass.

X-Q. 3. Do you know whether Mr. Elihu Thomson is associated with this company?

A. I believe he is a director in it and a stockholder.

X-Q. 4. Is Mr. Elihu Thomson associated with the Lynn works of the General Electric Company?

A. Yes, he is consulting engineer.

X-Q. 5. For many years he's had his office in the Lynn works of the General Electric Company, has he not?

A. Yes.

X-Q. 6. Referring to the so-called modifications stated in Q. 8, is it your understanding that the gaps made by the slots or grooves

would not be closed until the end or very near the end of the welding operation?

A. In the modification referred to, it is immaterial whether the slots are wide or not because the ridge formed by the cutting of the slots is evidently of about the same section as the blade to be welded thereto and in the upsetting part of the process the weld being enlarged may or may not come in contact with the metal on the other side of the slot on the carrier. The weld will be substantially a butt weld extending over the whole surface of the blade

(By Mr. Hall: The entire answer objected to as a mere volunteered statement in no wise responsive to the question.)

X-Q. 7. Now in answer to Q. 10 you said: * * * "an expansion of metal at the weld usually known as the burr which, in the particular modification described by Ferranti, would, in the final part of the operation, close up the gap made by the slots or grooves * * *." I ask you whether the closing of the gap would occur only at the close or near the close of the welding operation?

A. Before answering this question I want to draw attention of counsel for de Ferranti to the fact that my reply just quoted by him is in answer to a different modification than the one referred to in his previous question. With this understanding I will answer that in the modification referred to in Qs. 9 and 10 the closing up of the slot would take place during the last part of the welding operation when the metal is being upset by pressing the blade towards the carrier.

X-Q. 8. Is it your understanding that during the first part of the operation the carrier would contact with the opposed surface of the blade only at separated points on this surface?

A. It would in case of modification referred to in Qs. 9 and 10 but not in case of modifications referred to me in my reply to Q. 7.

X-Q. 9. And referring only to the modification referred to in Qs. 9 and 10, would the heating current during the first part of the operation be localized at these separated points?

A. It would be localized to exactly the contact surfaces which are being made at the beginning between the surfaces of the carrier in contact with the blade.

X-Q. 10. And referring to the modification of Qs. 9 and 10, is it your understanding that the carrier is provided peripherally with spaced apart tits or projections which contact at separated points with the opposed surface of the blade?

A. It is, but with the understanding stated by de Ferranti that these should be as numerous and as close together as possible consistent with producing the proper heating effect in order to obtain as large a welded surface of the blade to the carrier as possible.

Cross-examination closed.

(Counsel for Harmatta gives notice that at the final hearing he will refer to the following: Copy of provisional specifica-

tion of de Ferranti filed May 25th, 1903, No. 11,921, as found in the record of British patents in the Patent Office Library at Washington. De Ferranti's British patents Nos. 15,186 of 1903 and 11,921 of 1903. De Ferranti's United States patent No. 874,398, dated December 24th, 1907; 911,222, dated February 2nd, 1909; No. 1,148,221, dated July 27th, 1915. United States patent of Kleinschmidt, No 616,437, dated December 20th, 1898. United States patent to Cowdery, No. 481,663, dated August 30th, 1892. File wrapper and contents of de Ferranti's United States applications Serial Nos. 208,034 and 668,464.)

(Counsel for Harmatta will also urge at the final hearing all the grounds of his motion to dissolve filed May 4th, 1914, and October 28th, 1915.)

HERMANN LEMP.

Examination closed.

Adjourned subject to notice.

NOTARY'S CERTIFICATE.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

County of New York, State of New York, ss:

I, George E. Brown, a notary public within and for the County and State of New York, do hereby certify that the foregoing deposition of Hermann Lemp was taken on behalf of Johann Harmatta in pursuance of the notice hereto annexed before me at the office of Townsend & Decker, 149 Broadway, New York City, State of New York, on the 28th day of March, 1916; that said witness was by me duly sworn before the commencement of his testimony; that the testimony of said witness was written out by Miss Irene Lefkowitz in my presence; that the opposing party, Sebastian Ziani de Ferranti, was represented by counsel during the taking of said testimony; that the deposition was read by the witness before the witness signed the same; that I am not connected by blood or marriage with either of said parties nor interested directly or indirectly in the matter in controversy.

In testimony whereof I have hereunto set my hand and affixed

my seal of office at New York City, County of New York, this 28th day of March, 1916.

(Seal) GEORGE E. BROWN.

Notary Public—Richmond County Certificate Filed in New York County, No. 179; New York Register No. 7223. Term Expires March 30, 1917.

U. S. Patent Office.

UNITED STATES PATENT OFFICE,

Testimony for Harmatta. (Batch 2.)

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

New York, N. Y., April 8th, 1916.

Messrs. Spear, Middleton, Donaldson & Spear,
Victor Building,
Washington, D. C.

Gentlemen:

PLEASE TAKE NOTICE that on Thursday, April 13th, 1916, beginning at 11 a. m., at the office of Townsend & Decker, 149 Broadway, New York, before George E. Brown, Notary Public in and for the County of New York or some other duly authorized officer, the party Harmatta will proceed to take the deposition of the following witness in his behalf in the above interference:

JAMES H. GRAVELLL of Philadelphia Pa.:

and possibly others. The examination will continue from time to time until completed and you are invited to attend and cross-examine.

TOWNSEND & DECKER,
Attorney for Harmatta.

Due service of the above notice admitted this 10th day of April, 1916.

SPEAR, MIDDLETON, DONALDSON & SPEAR,
Attorneys for Harmatta.

620 Defendant's Exhibit No. 33.

UNITED STATES PATENT OFFICE.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

New York, N. Y., April 13th, 1916.

Testimony taken on behalf of Harmatta pursuant to the annexed notice at the office of Townsend & Decker, 149 Broadway, beginning at 11 A. M., April 13th 1916.

Present: MR H. C. TOWNSEND for Harmatta.
MR. WILLIAM F. HALL for de Ferranti.

JAMES H. GRAVELL.

JAMES H. GRAVELL, being duly sworn, deposes and says as follows in answers to interrogatories by Mr. Townsend:

Question 1. What is your name, age, residence and occupation?

Answer. My name is James Hardey Gravell; age 35; and business address is 1126 So. 11th Street, Philadelphia; occupation electrical engineer.

Q. 2. Have you any knowledge of or experience in the electric welding art and if yes, will you please state the nature and extent of it?

A. Upon my graduation from the Philadelphia High School I became associated with the Ellwood Ivins Tube Co., Oaklane, Philadelphia, where I had charge of experiments in electric welding. In 1900 I took up the work of experimenting in electric welding for the American Tube & Stamping Co., of Bridgeport, Connecticut, where I designed and built several special butt-welding machines and a machine for welding tubing. Since that time I have been connected with the Baldwin Locomotive Works of Philadelphia, the Philadelphia Electric Co. and the Hale & Kilburn Co., of Philadelphia, serving all in the capacity of an electrical expert During my carrer I have obtained quite a number of United States patents on welding.

Q. 3. Have you made any study or investigation of the history and development of the art of electric welding prior to 1903? If yes, please state the nature and extent of it.

A. At the year 1903 I had been engaged in electric welding for practically five years. I was specially familiar with welding as disclosed by the United States patents, having started an index on pat-

ents in the year of 1900 and was very careful to keep my index up to date.

(By Mr. Hall: Objected to for the most part as a mere conclusion and as secondary evidence.)

Q. 4. Are you familiar with the art of electric welding from the time of its origin to such extent as in your opinion to qualify you to testify from the standpoint of one ordinarily skilled in the art as it existed at the date May 25, 1903, when de Ferranti, party to this interference, filed his provisional specification unaccompanied by drawings in connection with proceedings for obtaining his British patent No. 11,921 of 1903?

(By Mr. Hall: Objected to as for calling for a mere conclusion.)

A. Having been connected with the industry for approximately five years at the time you state, namely May 25, 1903, both from a practical and engineering standpoint, I believe I am duly qualified to testify.

Q. 5. Have you read and considered the description forming the provisional specification filed by de Ferranti in connection with his application for his British patent No. 11,921 of 1903 and do you believe that you understand that description so far as it goes when taken apart from any drawings that may have been filed later by him in connection with his complete specification?

A. I have read the application carefully and believe I thoroughly understand it.

Q. 6. Referring to the first paragraph of the description forming that specification in which de Ferranti alludes to the difficulties which have been experienced in electric welding, will you please state how one skilled in the art at the time of the filing of that specification would understand that statement and particularly as to the nature of the difficulties and the particular kind of electric welding referred to? In giving your answer you may state what measures had been usually adopted in the art up to that time to overcome such difficulties.

(By Mr. Hall: Any and all testimony which the witness may give respecting prior art, structures or devices, is objected to upon the ground that it is incompetent, irrelevant and immaterial. It is so objectionable because permission has not been obtained for taking testimony in respect to such prior art structures, or has any motion been brought under rule 122 of the Rules of Practice directed to the non-patentability of the issue by reason of the prior art.)

A. At the time of Ferranti's application the only method of electric welding in which trouble had been experienced, when weld-

ing together two parts that differed greatly as regarding their thermal characteristics when heated at their point of juncture was what was known as the Thomson method. This difficulty is disclosed by Thomson in his original patent on electric welding in which he coins the term "electric welding." This patent is number 347,140. It is quite evident from the first paragraph in Ferranti's application that it was this difficulty disclosed by Thomson that Ferranti refers to. The heat in this system of welding depends on the thermal and electrical characteristics of the two bodies being welded. When one or the other of these characteristics differ greatly in the two bodies, unequal heating ensures, which results in either no weld or a defective weld. This was well recognized in the art prior to Ferranti's application and numerous methods had been proposed for eliminating this trouble. Many of these methods are disclosed by United States patents issued prior to Ferranti's application, namely:

347,140
347,141
396,010
434,530
487,302.

All these patents refer broadly in adjusting the volume of the metal in one part to that of the other part so that the thermal and electrical characteristics in the two bodies will be practically equal. In some cases, when welding a piece of large section to a small section, the larger section was reduced by forging or turning so that the section presented at the weld would be practically equal to that piece of the smaller section. In some cases the same result was obtained by holding the smaller piece close up to the weld in the copper clamp naturally a part of this process, so that it would keep the smaller piece which naturally attained a higher temperature than the larger piece, cool. When the larger piece was of such shape and size as to make it feasible, a lug or projection was provided by stamping or forging so as to present at the weld a section corresponding to that of the smaller piece. The difficulties that Ferranti refers to were well known to all skilled in the art at the time of Ferranti's application.

Q. 7. Will you please state more specifically what characteristics you refer to by the term "thermal characteristics" by explaining what would affect this characteristic and its relation to the operation of securing a proper heating of the metal to be welded.

A. Thermal characteristics are the properties of a substance relative to heat. The thermal characteristics which are considered in welding, as referred to by Ferranti, relate to the conduction of heat by the metal. The conduction of the heat by the metal depends on the cross-section of the path of escape of heat and on the nature of the metal. In Ferranti's case where he presents the end of a concave rod forming a blade to a disk which is relatively much larger than the blade, the periphery of which presents practically a

flat surface to which the end of the blade is to be welded, the thermal characteristics differ greatly because the escape of heat in the blade is restricted to a small path corresponding to the cross-section of the blade, whereas in the disk it is not restricted to a small path but quickly conducted through the whole disk. This would have a tendency to keep the disk cool because the heat generated in the disk by the current would be permitted to escape nearly as quickly as it was generated. This is said by Ferranti in his second paragraph only in slightly different words.

Q. 8. Will you please extend your answer to my last question by extending it to the prior art as it existed and was practiced prior to 1903?

(By Mr. Hall: Objection following Q. 6 is repeated.)

A. These thermal characteristics were well recognized prior to Ferranti's application as is illustrated in the patents already cited, which show that the thermal characteristics of the larger piece were altered by adjusting the volume of metal of the larger piece in the neighborhood of the welding point so that they would practically coincide with the thermal characteristics of the smaller piece, thereby producing equal heating in both bodies.

Q. 9. Assuming that one skilled in the art at the date of filing the de Ferranti provisional and as it existed at that date should proceed in the light of the art and of the de Ferranti provisional specification, taken apart from any drawings that may have been filed later in connection with the application for patent, to adjust the volume metal of the disk by forming intersecting sets of grooves inclined to one another, how would he proceed, in your opinion, in making said grooves as respects their spacing, width and depth? In giving your answer please state as fully as you can your reasons for any opinion you may express.

A. As Ferranti tells us in his specification that the object to be kept in mind is to insure a good weld and that only sufficient metal for this purpose, is to be removed, one skilled in the art at the time of Ferranti's application would, having this in mind, try to make the thermal characteristics of the two bodies as nearly equal as possible and would make very narrow grooves and of a depth practically equal to the distance between the copper clamp and the end of the blade. By making a number of thin grooves he would be enabled to restrict the path of the escaping heat to practically that of the path provided in the blade, thereby causing equal heating in the two bodies. By this method of procedure he would have adjusted the volume of the metal in the disk in the neighborhood of the welding point so that approximately equal heating would occur in both the end of the blade and the peripheral face of the disk in contact with the end of the blade.

Q. 10. Would the decreasing of the number of grooves affect what you call the thermal characteristics and if so, in what way?

A. The decreasing of the number of grooves, assuming the size of the grooves to remain the same, would tend to enlarge the cross-section of the path in the disk, thereby allowing a greater escape of heat from the welding point with a consequent cooling of that point, or, in other words, by reducing the number of grooves has the effect of cooling the disk at the welding point.

Q. 11. Assuming that one skilled in the art had proceeded to prepare the disk in the manner stated in your answer to Q 9, and had then proceeded to weld the blade to the disk or drum will you please state to what extent the edge of the blade would be involved in the weld? In giving your answer state how any result that you may specify would be brought about.

A. The blade would be brought in contact with the disk, the current would be passed from the blade to the disk, all the projections coming in contact with the blade formed by the cuts in the disk would become heated, the edge (by edge I understand it to mean the end of the blade) of the blade would become heated, pressure would be exerted between the two bodies, and upset would occur causing the projecting portions of the disk to mushroom or spread out, forming an arch construction from one projection to the other, resulting in a continuous surface under the blade to which the entire surface of the end of the blade would weld.

After recess:

Q. 12. Is there any other consideration that occurs to you that would guide one proceeding it cut the groove as suggested in the Ferranti specification in respect to the width of the grooves or the spaces between them?

A. As Ferranti says nothing about placing his blades in respect to the position of the grooves (and in fact when the invention is carried out by boring holes into the peripheral surface of the disk he says that the blades may be welded or arranged without particular reference to the position of the holes) it is quite necessary to have the grooves thin and quite numerous in order to make a like condition of the surface under each blade respectively; for otherwise, if the grooves are placed far apart, even if arranged regularly, it would require great care in placing the blades so that the same condition of surface would be presented to each blade respectively. This is especially true if the grooves are of any substantial width. As Ferranti does not caution us to be particular to place his blades according to the pattern produced by his groove, it naturally follows, in order to have the welding conditions the same at each blade respectively, that the grooves must be narrow and numerous, for it is only by this method that uniform results can be obtained. In a steam turbine it is essential that all the blades be equally spaced. Therefore, had Ferranti used any other style of groove except the kind which are narrow and close together, he would have been sure to tell us that these grooves would have to

be laid out according to a certain pattern so that a like condition of surface would occur under each blade respectively.

Q. 13. Have you ever had any actual practical experience in performing the operation of butt-welding by the Thomson Electric Welding process?

A. My duties at the American Tube & Stamping Co. of Bridgeport, Connecticut, in the years 1900 and 1901, required me to design butt-welders, to assemble the butt-welders and to actually operate the butt-welders which I had designed. It required my instructions as to how prepare the work which was to be welded and how to eliminate the burr which was formed in welding to produce the finished article. In some cases where a large section was to be welded to a small section to so adjust the volume in the large section so that it would not produce a cooling effect on the weld. My duties at this company required a knowledge of the hardening and softening properties in steel as applied to welding. It also required a knowledge of the chemistry of steel so that its welding properties could be determined beforehand. My duties at the Hale & Kilburn Co. of Philadelphia, required additional knowledge and a more expert manipulation of the welding machine, for at these works I was continuously confronted with new problems which were produced by the development of the steel interior finish of railway cars and of the all-steel construction of automobile bodies. At this company I was called on not only to design, construct and operate butt-welding machines, but was required to invent new processes, new apparatus and new products of manufacture as disclosed by my patents in the United States Patent Office. At one period of my career at the Hale & Kilburn Co. much of the welding consisted in welding a large section to a small section in which case I was obliged to adjust the volume of the metal of the large section so as to produce proper heating effects at the weld.

Direct examination closed.

Cross-examination without waiving objections made on the direct examination:

X-Q. 1. By whom are you now employed?

A. I have an engineering practice at 1126 So. 11th Street, Philadelphia. I am treasurer of the American Chemical Paint Co. of Philadelphia, and secretary of the Tilghman-Brooksbank Sandblast Co., all located at the same address.

X-Q. 2. It is your notion that you are testifying in this case as an expert?

A. It is.

X-Q. 3. Were you employed to testify in this case as an expert?

A. I was.

X-Q. 4. By whom?

A. By the Thomson Electric Welding Company.

X-Q. 5. Have you testified in other cases involving patents for electric welding machines or processes?

A. I have never been employed to actually testify but have been connected with another case relative to patents on electric welding.

X-Q. 6. Was that other case also in association with the Thomson Electric Welding case?

A. It was.

X-Q. 7. Do you recall what patents were involved in that case?

A. The case in question was the suit the Thomson Electric Welding Co. vs. Barney & Berry.

X-Q. 8. That suit was on the Harmatta patent which is involved in this interference, is it not?

A. It was.

X-Q. 9. Did you write out the substance of your testimony before testifying in this case?

A. I wrote out a discussion of the Ferranti interference, which was hardly the substance of my testimony today, although my testimony today was in accordance with the ideas set forth in my discussion.

X-Q. 10. And you referred to that memorandum in giving your testimony, particularly in answering Q. 13, did you not?

A. The only part I referred to was a tabulated list of patents to refresh my memory as to their patent numbers.

X-Q. 11. Didn't you refer to this memorandum in answer to Q. 13?

A. I did not.

X-Q. 12. During what period were you employed by the Baldwin Locomotive Works?

A. I believe it was the year 1904 although I'm not absolutely certain as to the exact date.

X-Q. 13. Was your employment for more or less than a year?

A. My employment was for less than a year.

X-Q. 14. What was your official rating at this time by this company?

A. I was hired by the Baldwin Locomotive Works by the Assistant Superintendent, Mr. Halsey, for the special purpose of developing a system of arc welding.

X-Q. 15. State your period of employment by the Hale & Kilburn Co.

A. I was employed by the Hale & Kilburn Co. for a period of five years, starting Jan. 1, 1910.

X-Q. 16. And what was your rating during that employment?

A. I was hired by Mr. E. G. Budd, Manager of the Company, especially for the purpose of developing spot-welding, butt-welding and arc-welding. My official title was engineer on electric welding.

X-Q. 17. Is it your notion that the description found in the de Ferranti provisional specification No. 11,921 is mis-descriptive of what is shown, for instance, in Figs. 1 and 2 of the de Ferranti complete specification No. 11,921?

(The witness is handed a printed copy of the de Ferranti British patent which includes the provisional specification, the complete specification and the drawings.)

(By Mr. Townsend: Objected to on the ground that it is improper cross-examination, the examination of the witness having been expressly confined on direct to the provisional specification which was unaccompanied by drawings and that the witness cannot be examined on cross as to the meaning of drawings not referred to on the direct and not in any way brought to his attention thereby. Counsel for Harmatta gives notice that he will hold opposing counsel strictly to the rule that by examining the witness upon those drawings he makes the witness his own and will be bound by the statements of the witness made in relation to those drawings. Counsel further reserves the right to move to strike out any cross-examination of the nature opened up by the question.)

A. This is the first I have seen of any drawings illustrating Ferranti's provisional specification. Fig. No. 1 illustrates fairly well that part of the specification where it says "Grooves may be cut across the edge of the ring." Fig. 2 illustrates diagrammatically without respect to the size of the grooves the part of the specification which says "Intersecting sets of grooves inclined to one another may be cut across the edge of the ring." These grooves are represented as being much wider than what I would have imagined from Ferranti's description, especially in view of the fact that Ferranti says the object to be kept in mind in this and in other modifications is to remove sufficient metal to enable the temperature to rise to the welding point * * * while at the same time leaving sufficient area untouched to insure due mechanical strength at the welding joint.

X-Q. 18. Now referring to what is shown in Fig. 2 of the de Ferranti specification No. 11,921, is it your notion that if one endeavor to make a weld with the projections spaced as shown in such figure, such upsetting of the projection would occur as to establish an arch from one projection to the adjacent projection?

(By Mr. Townsend: Same objection and notice it is agreed by counsel may stand without repetition as to all future questions of the same tenor as question 17.)

A. It will be noted in this drawing No. 2 that the projecting portions of the disk are of very slender cross-section and that only a small number of these projections engage the blade. Therefore the area of metal through which the current passes to the blade from the disk is of much less amount than the area of the blade. We therefore in this drawing have reversed the conditions which Ferranti says causes trouble. We now have a relatively large blade

to which are opposed very slender projections and unless the grooves are very shallow unequal heating will occur but in this case it will be the projections which get hot and not the blade. If, however, the projections are very short, if a weld is possible at all, it will occur as follows: The end of the blade will reach a welding temperature, the total projections will reach a welding temperature down to their roots, the body of the blade itself around the heated projections will become hot, and when the final welding pressure is applied which is necessarily called a welding operation, the blade will be forced against the projections upsetting them to such an extent that the blade at the welding temperature will reach the bottom of the groove and weld fast the same as when thermit is poured on relatively cool steel it raises the metal to the welding point and welds producing a weld across the entire blade.

(By Mr. Hall: The entire answer is objected to because it is a mere volunteered statement in no wise responsive to the question and simply serving to indicate the strong bias of the witness.)

X-Q. 19. Now having aired your views, please state whether, if one endeavors to make a weld with projections spaced as shown in Fig. 2 of the de Ferranti patent, such upsetting of the projections would occur as to establish arches between adjacent projections?

A. It is impossible to determine this answer from Fig. 2. This would all depend on how deep are the grooves.

X-Q. 20. Since you were retained in this case, have you made any actual experiment as a basis for the testimony which you have given and if so, when and where, and who was with you when the experiments were made?

A. I have made no tests or experiments since being retained in this case, but previous to that, however, I have often welded the end of a bundle of wires to a rod which presents almost an identical condition illustrated by Fig. No. 2 as well as that figure can illustrate.

(By Mr. Hall: All of the answer is objected to as a mere volunteered statement not responsive to the question except the part reading "I have made no tests or experiments since being retained in this case.")

X-Q. 21. About how long or what amount of time is required in making an electric weld of the character referred to in the de Ferranti provisional specification as you understand it?

A. It is impossible to determine from the de Ferranti specification how long it takes to make a weld. Nothing is stated regarding the dimensions of the material being processed and this is usually a determinning factor in the time required. Then, too, the speed of welding at the time of the Ferranti application was usually slower than it is at the present day.

X-Q. 22. How much time is required at the present day?

A. You would have to give me more specific information as to the time required in order to answer the question, that is, tell me the size of the blade and the size of the disk, and what variety of weld it is.

X-Q. 23. Well, I'll let you take, for instance, a turbine disk and a turbine blade, such as you know them; you may feel free to select the sizes and state them and tell us how long it would require "at the present day" and how long would have been required "at the time of the Ferranti application."

A. Taking the turbine disk as one-half of an inch thick and a blade of usual dimensions to correspond to that disk, and selecting the preparation of the disk as illustrated in Fig. 1 where grooves are cut across the face of the disk to make projections on the disk which correspond substantially to the shape and size of the blade, I would say, roughly speaking, the current would be on for a period of two seconds. This would not include the time of placing the work in the machine and removing the work from the machine. In the case which I have selected I do not believe the time would be materially different at the present day to what it was at the date of Ferranti's application.

X-Q. 24. And taking the case you have selected, are the parts to be joined pressed towards each other during the whole period the current is on?

A. The pressure applied is usually great at the start and as soon as the metal has been brought to a firm contact the pressure is reduced and at the completion of the weld the pressure is generally increased.

X-Q. 25. About how long does it take for the metal to become sufficiently plastic so that material change in the form thereof will occur taking the same example you have been referring to?

A. In the example which I have cited it would take practically two seconds because the current is stopped as soon as the metal is plastic enough. The final pressure referred to being only a momentary shove in the case of this light material which requires but an instant.

X-Q. 26. And does that shove take place before or after the current is stopped or shut off?

A. The current in usual practice in welding this light material, as in example, is cut off practically at the same instant the final pressure is applied.

Cross-examination closed.

634 Defendant's Exhibit No. 33.

IN THE UNITED STATES PATENT OFFICE.

DE FERRANTI

vs.

HARMATTA.

INTERFERENCE No. 36,709.

And now comes the party De Ferranti, above named, by his attorneys and moves as follows:—

(1) That questions 5, 6 and 7 and answers thereto, occurring in the deposition of Herman Lemp, the questions 6 and 8 and the answers thereto, occurring in the deposition of James H. Gravell, be struck out, or suppressed, because they relate solely to the alleged prior state of the art and not to the question of priority of invention between the parties to this interference, or the quesion of De Ferranti's right to make claims corresponding to the issue of the interference.

(2) For an extension of De Ferranti's time to take testimony for a period of thirty days, commencing to run after the final determination of the above motion to strike out or suppress.

Very respectfully,

SEBASTIAN Z. DE FERRANTI,

By SPEAR, MIDDLETON, DONALDSON & SPEAR, *Attys.*

IN THE UNITED STATES PATENT OFFICE.

DE FERRANTI

vs.

HARMATTA.

INTERFERENCE No. 36,709.

Washington, District of Columbia, ss:

I, James M. Spear, being duly sworn, depose and say that I am of counsel for the party De Ferranti, above named, and am familiar with the proceedings heretofore taken in this interference.

That the testimony taken on behalf of Harmatta relates principally to the right of the party De Ferranti to make claims corresponding to the counts of this interference, and in order to meet this testimony deponent thinks it highly desirable to examine one or more experts specially skilled in the art of electric welding.

Deponent's firm communicated with their principal, who resides

in Great Britain, in respect to this matter and also investigated available experts in this Country. The latter experts, of which deponent's firm had knowledge, were found on investigation to be so connected with Harmatta, or his assignees, that they would be unavailable on behalf of the party De Ferranti in this case.

It was hoped to take the testimony of De Ferranti in this Country but it was found that he is now engaged in making war ammunitions on behalf of Great Britain and cannot leave that country for the purpose of coming to this Country to testify in the case.

The questions involved herein are unusually technical and it is consequently very difficult to find one competent to testify, particularly in view of the connection of the many experts in this line with the party Harmatta or his assignees.

Furthermore deponent sayeth not.

JAMES M. SPEAR.

Sworn to and subscribed before me this first day of June, 1916.

BENNETT S. JONES,

DE FERRANTI

vs.

HARMATTA.

BEFORE THE EXAMINER OF INTERFERENCES.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

THOMAS EWING,
Commissioner of Patents.

6—1652.

This case is before me on motion by De Ferranti, filed June 2, 1916, asking (1) that certain questions propounded to Harmatta's witnesses Lemp and Gravell, together with the answers thereto, be suppressed; (2) that De Ferranti's time for taking testimony be extended to run thirty days from the determination of the first part of the motion.

(1) There is no sufficient reason why the examiner should attempt to pass upon the propriety of the questions objected to at this time. It is always difficult to rule satisfactorily upon a few segregated questions without considering other portions of the record. This part of the motion will be continued until final hearing.

(2) The motion to extend De Ferranti's time will be granted.

The motion to strike out is deferred until the case comes on for final hearing on the merits.

The second part of the motion is granted and De Ferranti's time for rebuttal testimony is fixed to expire July 8, 1916.

Final hearing September 8, 1916, at 11 A. M.

H. E. STAUFFER,
Examiner of Interferences.

BEFORE THE EXAMINER OF INTERFERENCES.

INTERFERENCE No. 36,709.

DE FERRANTI

vs.

HARMATTA.

It is hereby stipulated and agreed that De Ferranti's time for taking testimony in rebuttal, in the above entitled case, be extended two months from the date now set. The evidence required in rebuttal will be of an expert character largely, and in correspondence with the British Patent Attorney representing De Ferranti it has been ascertained that Mr. De Ferranti and every other leading expert is engaged in Government work in England, and it is not only impossible to secure the attendance of Mr. De Ferranti or any English expert on this side but we are still further advised that no leading expert could give attention to this matter at the present time even to answer interrogatories or to give evidence orally under a stipulation, and it is therefore imperative that further extension be secured of the time now set. As counsel for Harmatta have expressed themselves as quite willing to stipulate for this further extension it is urgently requested that the Office approve the stipulation without question under the circumstances.

SPEAR, MIDDLETON, DONALDSON & SPEAR,
Attorneys for Ferranti.

Not admitting that testimony properly in rebuttal of that given for Harmatta could be of such nature that it cannot be taken in this country at all, we consent to an extension of De Ferranti's time one month.

TOWNSEND & DECKER,
Attorneys for Harmatta.

IN THE UNITED STATES PATENT OFFICE.

BEFORE THE EXAMINER OF INTERFERENCES.

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

INTERFERENCE No. 36,709.

Messrs. Townsend & Decker,
149 Broadway, New York, N. Y.

Gentlemen:

Please take notice that on Friday, the 10th day of November, 1916, at 10 o'clock in the forenoon, at our office, Victor Building, Washington, D. C., before Bennett S. Jones, a Notary Public, or other competent officer, we shall proceed to take testimony in the above entitled case on behalf of the party de Ferranti.

The witness to be examined is Frank L. Dyer, whose office address is 31 Nassau Street, New York City, and perhaps others whose names and addresses are not now known but of which you will be given due notice.

Proceedings will be adjourned from day to day and to such time and place as may be found necessary.

You are invited to attend and cross-examine.

Respectfully,
SPEAR, MIDDLETON, DONALDSON & SPEAR,
Attorneys for de Ferranti.

Service accepted this 6th day of November, 1916.
TOWNSEND & DECKER,
Attorneys for Harmatta.

UNITED STATES PATENT OFFICE.

In re Interference:

DE FERRANTI

vs.

HARMATTA.

No. 36,709.

Washington, D. C., November 10th, 1916.

Testimony taken on behalf of De Ferranti pursuant to notice annexed hereto commencing at the Office of Spear, Middleton, Donaldson & Spear, Victor Building, Washington, D. C., Friday, November 10th, 1916, at 10 o'clock in the forenoon before Bennett S. Jones, Notary Public.

Present: MESSRS. H. C. TOWNSEND and C. F. TISCHNER, on behalf of Harmatta;
WILLIAM F. HALL, on behalf of De Ferranti.

FRANK L. DYER, ESQ.

FRANK L. DYER, ESQ., a witness produced on behalf of De Ferranti, having been first duly sworn to testify to the truth, the whole truth, and nothing but the truth in answer to interrogatories, testified as follows:

Question 1. What is your name, residence and occupation?

Answer. Frank L. Dyer, age 46, Montclair, New Jersey: I am engaged in the manufacturing business with factories at Bloomfield, New Jersey, and Wyandotte, Michigan.

Q. 2. The case in which your testimony is being adduced is an interference pending in the United States Patent Office relating to methods of electric welding and involving the question of the disclosure of this invention in and by a certain foreign British patent. What experience have you had which qualifies you to testify as an expert in this case?

A. I have been intimately connected with matters relating to patents and inventions for upwards of thirty years and have had occasion to prosecute before the Patent Office several thousand applications for patents relating to many and diverse arts including the art of electric welding. I have made many inventions myself on which over one hundred applications for patents have been filed, many of them relating to electrical subjects. As a result of my work as an inventor, although not an engineer, I was elected an associate of the American Society of Mechanical Engineers. I was in active practice as a Patent Lawyer from 1892 to 1908, during

(By Mr. Townsend: Same objection and notice. Also objected to as leading.)

A. I do. The De Ferranti provisional specification refers to the difficulties experienced by the patentee "in electrically welding together the two parts which differ considerably as regards their power of rising to the required welding temperature when heated at the point of junction" (page 1, lines 6-8). It is, therefore, clear that the specification relates to an electric welding process in which the welding heat is secured by the resistance of the two pieces to be joined as distinguished from processes in which an electric arc is used. In a broad and general sense this is the so-called Thomson process originally invented and patented by Prof. Elihu Thomson about the year 1886. In the De Ferranti provisional specification the inventor refers to the desirability of so carrying the process out as to secure substantially uniform welding conditions at the point of junction when the two parts which are welded together differ considerably in mass, or in other respects differ considerably as regards their power of rising to the required welding temperature. The specification discloses a number of ways by which the welding process may be carried into effect, some of which, in my opinion, comply with the limitations of the claims in issue herein. I have prepared and present herewith drawings illustrating the several suggestions made by De Ferranti and disclosed by him in the provisional specification. Figure 1 illustrates the suggestion that "grooves may be cut across the edge of the ring" (lines 20 and 21). With this suggestion, assuming the invention is carried out in connection with welding a series of turbine blades to a suitable carrier, the turbine blades will be welded to projections on the carrier by a butt-welding process and not by the particular method disclosed in the claims in issue. Figure 2 discloses the arrangement suggested by De Ferranti in the statement "or several grooves may run circumferentially completely around the edge" (page 1, lines 21 and 22). In this figure I also illustrate on an enlarged scale the under face of one of the turbine blades showing the area of the several welds by section lines. These welds in Figure 2 correspond to the spots or distinct or separate spots separated from one another by well defined areas of no union as defined in the claims in issue. In other words, with the arrangement shown in Figure 2, the welds occupy only a part of the surfaces to be secured together, thus localizing the current within circumscribed paths and effecting a more rapid and economical welding operation than when the entire area of the surfaces constitutes the weld. In Figure 3, I illustrate the suggestion of De Ferranti described by the words "or, again, intersecting sets of grooves inclined toone another may be cut on the edge of the ring" (page 1, lines 22-23). In this figure I also show on an enlarged scale the underside of one of the parts (in this case a turbine blade) illustrating by sectional lines the well defined spots or areas constituting the plurality of welds and by means of which the

welding current will be localized within restricted or circumscribed areas. This particular figure is that of the De Ferranti drawing in interference and manifestly it corresponds with the restrictions and limitations of the claims. In Figure 4, I illustrate the arrangement which is described by the words "radial holes may be bored a short distance into the edge, either arranged in patterns, so as to leave intervening projections of untouched metal to which the blades may be welded" (page 1, lines 24-26). The weld in this case corresponds substantially to Figure 1, is coextensive with the entire area of the turbine blade and does not correspond with the limitations of the issue. In Figure 5, I illustrate the arrangement disclosed in the De Ferranti provisional specification by the words "or arranged without particular reference to the position of the blades" (page 1, lines 26-27). In this figure I show on an enlarged scale the under face of the turbine blade illustrating the area of the welds which are arranged in spots or defined areas so as to localize the heating current and this arrangement also, like those of Figures 2 and 3, corresponds to the limitations of the issue. In Figure 6, I illustrate the suggestion made in the provisional specification and described by the words "Again, the result aimed at may be secured by boring holes through from face to face of the ring at a radius slightly less than that of its outside edge." (Page 1, lines 32-33). With this suggestion the area of the weld will correspond to the entire engaging face of the turbine blade and therefore this particular suggestion does not correspond with the limitations of the issue. In Figure 7, I illustrate the suggestion described in the provisional specification by the words "the ring may be built up of two or more thinner rings held in their relative positions by distance pieces or in any other convenient manner, the blades being then welded in position on their outside edges" (page 1, lines 34-37). In this figure I also illustrate on an enlarged scale the bottom face of the turbine blade illustrating by sectional lines the area of the welds which are thus located in spots or well defined areas by which the heating current will be localized. Finally, in Figure 8, I illustrate the arrangement described by De Ferranti in the provisional specification by the words "Again, the ring may be built up of a set of laminae, the edges of which are notched, the laminae being assembled in such a way that the notches are "stepped" with regard to each other, the intervening projection of metal thus following the shape of the turbine blades to be welded to them." (Page 1, line 38; page 2, line 2). Assuming that with this arrangement the laminae are arranged closely together so that the projections referred to will constitute a substantially continuous surface to which the turbine blades are electrically welded, I find that with this suggestion the weld will occupy substantially the entire area of the bottom face of the turbine blade and will not correspond to the limitations of the issue. I do find, however, that the De Ferranti provisional specification, as illustrated in Figures 2, 3, 5 and 7, suggests a method of welding electrically two pieces of metal together

By spot welding, as I understand it, is meant the welding together of metallic pieces or surfaces, by a plurality of separate isolated welds separated by surfaces of non-union, the heating current being confined to or circumscribed by the restricted areas corresponding to the welds. In the De Ferranti divisional specification, means are suggested and methods are disclosed by which a satisfactory welding operation can be effected between two metallic pieces, one of which may be of enormously greater mass than the other, and by which the welding conditions as to these highly dissimilar parts may be made substantially constant. But De Ferranti in his provisional specification makes a further suggestion, and that is the welding of two metallic pieces together in a series of isolated defined spots separated by areas of non-union, and this latter suggestion is just as applicable to the securing together of metallic pieces having the same mass as the securing together of metallic pieces having widely different masses. Now referring to the Rietzel patent, to which you call my attention, particularly to Figures 1 to 3, I find that this patent discloses the same suggestion made by De Ferranti of securing together two metal pieces by a series of isolated welds, by which the current will be localized, but Reitzel suggests thus spot welding together two metal pieces of substantially the same mass, but the method followed, as I have said, is the same whether the masses are different or are substantially equal. In Figure 3, Reitzel shows one of the metal pieces as being formed with projections which are cast thereon, so that he is here dealing with a cast metal object as distinguished from sheet metal produced by a rolling operation and in which casting would be impossible. Now, so far as I can see, the projections shown by Reitzel, in Figure 3, correspond exactly to the projections disclosed by De Ferranti as being formed by cutting cross grooves in the ring, as I show in Figure 3 of the Exhibit, "Dyer Sketch." The only difference is that with Rietzel the projections are cast on one of the objects to be welded while with De Ferranti the projections are formed by cutting grooves in the metal object presumably by means of a milling machine. If the suggestion of De Ferranti is carried out for securing together two flat cast plates, such as Rietzel shows in Figure 3 of his patent, I am not able to perceive the slightest difference between the methods suggested by the two inventors with the single exception that with Reitzel the projections which define the spots and localize the current are formed by casting, while with De Ferranti the projections which define the spots and localize the current are formed by cutting grooves in the surface of the plate.

Recess.

Q. 7. Please consider the alleged prior art items referred to in the testimony adduced herein on behalf of the party Harmatta and state whether or not the disclosures which you find therein in anywise alter the opinion you have expressed that the invention defined by the issue of this interference is fully disclosed in the De

Ferranti British provisional patent to which you have referred? You may give your reasons for any statement you may make in this connection.

A. By prior art items I understand you mean the prior patents and publications referred to by the witnesses Lemp and Gravell, whose testimony has been taken on behalf of Harmatta, and with this understanding I will state that I have considered the same and do not find therein anything that in any way alters or effects the opinions I have already expressed concerning the sufficiency of the Ferranti provisional specification. Mr. Lemp refers to Thomson patent No. 347,141 as showing in Figure 8 a knife blade which "is champered to meet the diameter of the ax handle." I do not find this specifically described in the patent but I see no reason to question the correctness of Mr. Lemp's statement. This, however, is purely butt welding in which the weld occupies or is co-extensive with the entire area of the surfaces to be joined and is in no way analogous to or suggestive of spot welding. Mr. Lemp also quotes from the Electrical World of Dec. 25, 1886, in which the statement is made that when the pieces to be joined are of different metals, or of different sections, "the abutment or meeting point is placed nearer the clamp carrying the most resisting metal: or, the piece of smaller section, or the metal most readily fused, as the case may be, is so placed as to project least, for the purpose of favoring the accumulation of heat in the other piece," and Mr. Lemp also quotes from this article the statement that when the pieces are of different diameters "the end of the large piece is reduced to the size of the smaller before attempting to effect the weld." All of this I am quite prepared to admit was the practice in connection with butt welding but it has no relation or analogy to the more recent art of spot welding in which the pieces to be joined are secured together by a series of separate isolated welds which localize the heating current and which are separated by surfaces of non-union. Mr. Lemp also referred to Thomson patent No. 396,010 and calls attention to the knob or projection *b* to which the ends of the tool handle is butt welded by the old and well known butt welding method, even to the extent of the formation of a burr or fin as shown in Figure 12, which requires to be removed by a separate finishing operation but which presents no difficulty in spot welding. I see no analogy in this patent to spot welding in any sense of the word. All that it shows is a butt welding method. It does not disclose the welding together of two metal pieces by a series of isolated welds which localize the current and which are separated by surfaces of non-union. Mr. Lemp also refers to Thomson patent No. 434,530, Figure 10, but makes no comment thereon, at least specifically. I do not know whether this Figure shows a rod, bar, or plate. All that it clearly shows is the formation of two butt welds and is in no way suggestive of spot welding. He also refers to Thomson patent No. 487,302, Figure 4, showing a piece of carriage hardware, not otherwise identified, provided with two projections to which two pieces A and B are welded by an ordinary

butt welding operation. It is impossible to say whether the pieces A and B are rods, bars, or plates, but it is clear that nothing is here suggested of a spot welding process in which two metal pieces are joined by separate isolated welds localizing the current and separated by surfaces of non-union. Mr. Lemp finally refers to Figures 23, 25, 52, 56, 57, 76, 78 and 95 of an article on electric welding appearing in the Iron Age of January 28th, 1892, but I do not find in any of the examples shown in this publication the suggestion of spot welding two metallic pieces together, as I have explained.

I do not understand that Mr. Lemp refers to these instances of the prior art for the purpose of showing spot welding but only for the purpose of showing "that the sections of the parts to be welded electrically together should be modified so as to be as nearly equal as possible to produce equal heat." At best this merely relates to the suggestion made by De Ferranti that when the parts to be welded together differ widely in their thermal characteristics or mass, provision is to be made to so equalize conditions as to bring the adjacent surfaces to the welding temperature with substantial uniformity. The references to which Mr. Lemp refers do not, so far as I can see, have any relation whatever to the second suggestion made by De Ferranti, namely, that two metallic pieces may be joined by a series of separate isolated spots localizing the current and separated by surfaces of non-union. The references to the prior art made by Mr. Gravell seem to relate to prior Thomson patents, substantially all of which were considered by Mr. Lemp. According to Mr. Gravell: "all these patents refer broadly in adjusting the volume of the metal in the one part to that of the other part, so that the thermal and electrical characteristics in the two bodies will be practically equal." This also relates only to the suggestion of De Ferranti regarding the welding of two pieces together when they have widely different characteristics and has no connection whatever with the other suggestion made by De Ferranti of securing two metal pieces together by a series of spot welds localizing the current and separated by surfaces of non-union. In fact, so far as I can judge, the testimony of both Mr. Lemp and Mr. Gravell seems to be directed essentially to the single point of securing uniform terminal conditions when two pieces widely different in mass are to be welded together. As I understand it, the claims in issue have nothing whatever to do with this particular feature. They appear to have overlooked entirely the other suggestion made by De Ferranti of spot welding two metallic features together by means of a series of isolated separated welds which cause the current to be localized and restricted to the spots in the same way as suggested in the Dietzel patent. It seems to me that it is quite clear that this latter suggestion is independent of the former suggestion and is just as applicable to the welding of metallic pieces which are of practically the same mass as the welding together of pieces that differ widely in mass. In point of fact, the Rietzel patent discloses how this method can be carried out in connection with

sheet metal or with cast plates which presumably do not differ materially in mass.

Q. 8. The witness Lemp in answer to Q. 10 refers to "The conditions laid down by De Ferranti to insure the greatest mechanical strength at the welded joint," and in answer to cross-question 10 in referring to the projections he says "these should be as close together as possible consistent with producing the proper heating effect in order to obtain as large a welded surface of the blade to the carrier as possible." Do you find any warrant in the De Ferranti provisional specification for these statements, or any statement which would lead you either to agree with, or disagree from, the statement of Mr. Lemp?

A. No, I do not find anything in the provisional specification confirming these statements of Mr. Lemp. In fact, it would appear to me that the provisional specification gives precisely the opposite constructions. The statement in the provisional specification—"at the same time leaving sufficient areas untouched to insure due mechanical strength in the welded joint"—conveys to my mind the meaning that the area of the isolated welds is made large enough to give the necessary mechanical strength to the joint and that if a joint will be mechanically strong enough by utilizing for example 10 per cent of the area of the adjacent surfaces for the total, or aggregate, welding area, then 90 per cent of the opposed surfaces will represent areas of non-union. Mr. Lemp takes the position that with the provisional specification the instructions at all times are to secure the greatest possible mechanical strength, but, as a matter of fact, all that De Ferranti seeks to obtain is "due mechanical strength." If the maximum mechanical strength was desired assuming that all conditions are equal, then a joint which occupied the entire area of the turbine blade would be obviously stronger mechanically than one which occupied only a portion of that area. But De Ferranti does not indicate any preference for the former as against the latter, and therefore I should say that any skilled person reading the provisional specification and finding the suggestion of spot welding disclosed therein would so arrange the spots, or projections, as to give only sufficient, or in other words, due mechanical strength to the joint, and hence would seek to minimize the total area of the welded portion and to maximize the total area of non-union.

Q. 9. Testifying in this case Mr. James H. Gravell in answer to Q. 9 in part said as follows: "As Ferranti tells us in his specification that the object to be kept in mind is to insure a good weld and that only sufficient metal for this purpose is to be removed * * *." Do you find in the De Ferranti provisional specification any warrant for this statement?

A. No, I do not. The reasons for this opinion, I have pointed out in connection with substantially the same statement made by Mr. Lemp. All that De Ferranti considered necessary was to secure a weld of due mechanical strength and this is what will define the extent of the total welded area. If sufficient mechanical

X-Q. 21. Are they practically a reproduction of the sketches?
A. They are.

X-Q. 22. At the time you made the sketches had you made a study of the drawing and specification of the De Ferranti application involved in the interference 36,709?

A. No, I cannot say that I had. I have purposely refrained from considering the complete specification of Ferranti and limited myself to a critical study of the provisional British specification. I cannot say that I have not seen the drawings filed with the complete specification but I have never critically examined them. I did not see the Ferranti American specification involved in this interference until today. The sketches made by me were, so far as I could, made from a consideration of the provisional specification alone.

X-Q. 23. As a matter of fact, the drawings introduced as Dyer drawings are the same as some of the drawings of the complete British application of De Ferranti, excepting as to the added sectional figures appearing to the left of Figures 2, 3, 5 and 7, is not that the case?

A. Yes, substantially so, for example, my Figure 1, which was my understanding of the provisional specification, corresponds to Figure 1^a of the De Ferranti complete specification but differs in respect that the ring supporting the blades is shown as corresponding to the width of the blades, whereas in Figure 1^a of the complete specification, the blades overhang the ring. Of course, having seen the drawing forming part of the complete specification, one's mind probably consciously adopts forms of illustration. But to a person familiar with turbine construction, I should say that the drawings, as I have made them, from the provisional specification, would correctly illustrate the disclosures thereof.

X-Q. 24. In turbine construction is the aim of the constructor as a general rule, to form as complete, strong and extensive a union or homogeneity of structure of the blade and carrier having in view the great circumferential stresses to which the blades are subjected in the operation of the turbine?

A. No. It is only necessary that there shall be due mechanical strength between the turbine blade and the carrier.

X-Q. 25. Do you mean that there is no factor of safety considered or taken into account in the art of turbine construction, or to otherwise put it that the constructor aims to keep this union down to what he may consider due strength?

A. I mean that it is not necessarily the aim of the constructor to obtain the greatest or maximum mechanical strength. All that he desires is to secure due mechanical strength, having regard for a proper factor of safety. What I mean by this I can illustrate by an experience which we had at the Edison laboratory when Mr. Edison was developing a railroad car for operation with the storage battery. He wanted to make the car as light as possible and made careful tests of standard railroad cars to see in what respect they could be lightened. He discovered, for example, that the

steps of standard railroad cars have a breaking strain of 130,000 pounds, which of course is many times more than the maximum strain to which they would ever be subjected. Now this, as I understand it, is true with turbine construction. If we refer to the Ferranti complete specification, we find, for example, that in Figure 5 the turbine blade is welded to the carrier thoughout its entire area, whereas in Figure 3, for example, the area of the weld is probably less than 50 per cent of the total. No preference is expressed by De Ferranti for one construction over the other and as he is one of the greatest engineers and machine designers in the world, there is no doubt that when the weld is limited to a part of the available area sufficient strength for the purpose is secured. And, of course, the amount of strength between the welded surfaces depends upon the use to which the process is put. If the strains tending to separate the part are not severe, the area of welding will be proportionately decreased.

Adjourned until tomorrow at 10 A. M.

November 11th, 1916.

Met pursuant to adjournment. Parties present as before.

Cross-examination of Mr. Townsend continued.

X-Q. 26. Have you refreshed your mind as to the nature of the welding operations which you allude to at the end of your answer 2 as having been witnessed by you and can you now state definitely what those operations actually were?

A. Yes, I find that the operations referred to were those described and claimed in patent No. 645,066 to Brown & Morse in which carbon electrodes were employed to produce the heating effect.

X-Q. 27. In those operations which you state were actually witnessed by you, was union effected by a solder or spelter interposed between the pieces to be joined and brought to a proper temperature by means of the heat conducted from the carbon electrodes?

A. That I do not recall. I observe that the claims of Brown & Morse, appearing in the Official Gazette, refer to "welding or brazing." With a welding operation the joint is secured by an actual fusion of the surfaces of the pieces to be joined. With a brazing operation an additional metal of lower melting point is used to effect the joint. At this date, almost 20 years after witnessing the operation, I do not recall whether the process was carried out with or without a spelter.

X-Q. 28. If you do not recall whether the union was effected by spelter, how can you say that you witnessed actual welding operations?

A. I referred to this matter only in a most incidental way and had no idea that it would be considered of more than passing in-

terest. I had a very fixed and definite recollection that the subject matter of the interference referred to was an electric welding process, but when I now refer to the claims and find that they speak of brazing also, I do not like to state positively that the operations I witnessed may not have been electric brazing. However, whether the operation was welding or brazing the two methods are very closely allied.

X-Q. 29. Have you ever personally done electric welding by an actual welding operation as distinguished from an operation which is in fact soldering, the solder being heated by an electric current?

A. No, I have not.

X-Q. 30. Do you recognize a well-defined difference in principle between electric welding by the what is some times called the electric resistance process wherein the pieces are brought to welding temperature by the development of internal heat in them and an electric soldering process, such as that which may have been witnessed by you as you now state?

A. I recognize fundamental distinctions between a process in which heat is developed by the internal resistance of the metals to be joined and that in which heat is developed in an exterior mass such as a carbon electrode. There is, of course, a distinction between electric welding in which the surfaces to be joined merely reach a condition of plasticity and electric soldering in which a metal having a lower melting point is actually melted and becomes liquid, but the two processes may be very closely allied. If, for example, the separate pieces C' shown in Figure 5 of the Rietzel patent were properly chosen with respect to melting points of the plates to be joined, I should say that such a process would be electric soldering or brazing.

X-Q. 31. Have you ever at any time witnessed or performed the operation of electric welding by the Thomson process as applied to a butt welding of pieces of metal?

A. I don't recall that I have.

X-Q. 32. Would the process described by De Ferranti in his provisional specification be carried out if the intersecting grooves were made narrower than those shown in your drawing, Figure 8, in proportion to the size of the intervening projections shown in your drawings?

A. I should say that so far as De Ferranti's suggestion of spot welding is concerned, it would be carried out in any connection where there is a series of separated and isolated welds localizing the current and with surfaces of non-union. According to the instructions of the De Ferranti provisional specification, the total combined area of these isolated welds is sufficient to give due mechanical strength. When the process is used in an art requiring great mechanical strength the total area of the isolated welds should be greater than when the process is carried out in an art where great mechanical strength is not required.

X-Q. 33. Could the approximately equal heating referred to by

the patentee in his provisional specification in the clause stating that "the invention, therefore, consists broadly in adjusting the volume of the metal of the disc, etc.," be secured if the grooves as shown in your drawing Figure 3 were made relatively narrower than therein shown? What I mean is in proportion to the size of the intervening projections.

A. The size and depth of the grooves defining the character of the projections would, in my opinion, be a matter of determination for each class of work to which the process is applied. The grooving of the larger element in any way, however ineffective, would be an approach towards uniformity and how nearly uniform the conditions must be to comply with this part of De Ferranti's invention I would not undertake to say because, as I understand it, this feature is not involved herein. When, however, the question of spot welding is concerned and is applied, for example, to securing together two metallic bodies of approximately the same mass, this question of uniformity of heating conditions does not arise at least to a conspicuous extent. In the latter case then the question of the selection of the size, location, and number of the projections which define the separate welds is purely a question of securing the de sired mechanical strength.

X-Q. 34. Your answer does not seem to me to be directly responsive to my question and I will ask you to endeavor to make an answer conforming to the question, will you please try to do so?

A. I endeavored, so far as I could, to answer your question. I intended to have the inference drawn therefrom that so far as this particular feature of De Ferranti's invention is concerned there might be occasions in welding two parts together where in order to secure approximately equal heating the grooves should be made narrower than I show in Figure 3. But I felt that in entire fairness I should point out that when the process is applied to securing together pieces of substantially the same mass, this question of uniformity takes care of itself, and therefore the matter of selection of the size, number and location of the projections is purely a matter of securing the necessary mechanical strength in the joint.

(Objected to as irresponsive.)

X-Q. 35. Would the electrical welding of turbine blades to discs be an occasion of welding two parts together where in order to secure approximately equal heating the grooves could be made proportionately narrower in proportion to the size of the intervening projections than is shown in your drawing, Figure 3?

A. No, I should say not. For instance, my Figure 3 corresponds substantially to Figure 2 of De Ferranti's complete specification and this latter figure illustrates the proportion of grooves and projections used when the turbine blade is to be welded to the carrier. Of course, these proportions might be varied according to the capacity and type of the turbine. This matter is largely a

question of determination, as I have before said, depending upon the special conditions of each case.

X-Q. 36. I assume that your last answer is to be understood as in the negative to the question, am I right?

A. No. Not necessarily. What I mean is that in one turbine construction the proportion shown in my Figure 3 may be correct to secure equal heating effect. In another turbine construction the grooves might be narrower and in the third construction they might be wider.

X-Q. 37. To what differences of turbine construction do you allude in your last answer?

A. Differences in type and capacity. For instance, with a turbine of the Level type having enormously high shaft speeds the conditions are different from turbines of the Curtis type having much lower shaft speeds. A turbine with a small rotor turning at a very high speed presents different conditions from a turbine with a rotor of large diameter and turning at a relatively low speed.

X-Q. 38. How would these differences mentioned by you affect the proportion of width of groove to width of projection in the arrangement shown in your drawing Figure 3.

A. Still having reference to the feature of De Ferranti's invention in which he desires to secure uniformity of heating conditions, the question of varying the size and proportion of the grooves would depend largely upon the relative masses of the blade and carrier as well as the materials of which they are formed. The question of speed bears directly upon the question of mechanical strength, since the centrifugal pull on the blades in the high-speed turbine is very large and the area of the welds would have to be selected to give due mechanical strength to resist the tendency of the blades to fly off. I should therefore say that in turbine construction the proportioning of the grooves would be a matter for separate determination in each case.

X-Q. 39. What is the turbine construction alluded to in your answer 36 in which the grooves might be narrower as stated by you in that answer?

A. I have no particular construction in mind. What I meant was that constructions might be encountered in which a narrowing of the grooves might be desirable.

X-Q. 40. In making your sketch how did you arrive at the proportion of width of grooves and width of projections shown in your Figure 3?

A. I made the sketch from the provisional specification but, as I stated in my direct examination, previous to that time I had seen the drawing of the complete specification. I assume, therefore, that I followed unconsciously the mental impression of Figure 2 of the complete specification.

X-Q. 41. Is there any statement in the provisional specification of Ferranti that the areas of non-union should be made as extensive as possible?

A. Yes, I understand the expression "while at the same time leaving sufficient areas untouched to insure due mechanical strength in the welded joint" to mean precisely this. If De Ferranti had said that at all times the point should have the maximum mechanical strength, I would not get this impression, but when he says that due mechanical strength is all that is required, then it seems to me that this question of due strength is what determines the extent of the isolated welds, and therefore, when two pieces are secured together in which great mechanical strength is not necessary, the areas of non-union will be large.

X-Q. 42. But what about the statement that the objects is "to remove sufficient metal to enable the temperature to rise to the welding point as explained above"? Do you interpret that as an instruction to make the areas of non-union as extensive as possible?

A. No, I interpret that to mean that when the process is to be carried out for welding together two pieces of dissimilar mass sufficient metal is removed from the larger mass as to secure uniformity of heating conditions, the amount of metal removed depending upon the difference between the two masses.

X-Q. 43. Do you find any statement in the De Ferranti provisional specification that the invention is designed for or applicable to securing together of metallic pieces having the same mass?

A. No, I do not find any direct statement to the fact and I have not at any time asserted that there is any such statement in the provisional specification. All that I have asserted is that the method is just as capable of being carried out with objects of the same mass as in the Rietzel patent, which discloses the same method.

X-Q. 44. Would the methods disclosed by the provisional specification as you understand it be just as useful in the welding of pieces of the same mass as in the welding of pieces of a different mass?

A. So far as spot welding is concerned, yes. In this connection I quote from the standard hand book for electrical engineers (McGrow-Hill Book Company, New York), where on page 1728 the statement is made "To overcome the difficulties due to non-uniform temperature distribution, what is known as spot welding has been developed. Spot welding usually consists of punching the surfaces to be welded in such a way that a series of joints of equal and definite area are made between the two, the whole object of the spot weld process is to reduce the welded point to an area of definite and uniform dimensions." The copy of the hand book from which I have read was published in 1915.

(By Mr. Townsend: The reference to the hand book is objected to as incompetent because the author of the statement, whose name appears at the head of the article, cannot be cross-examined, and as immaterial because of the late date of the hand book being 1915.

UNITED STATES PATENT OFFICE.

ADOLPH F. RIETZEL, OF LYNN, MASSACHUSETTS, ASSIGNOR TO THOMSON ELECTRIC WELDING COMPANY, OF LYNN, MASSACHUSETTS, A CORPORATION OF MAINE.

UNITING THE COMPONENT PARTS OF COMPOSITE SHEET-METAL STRUCTURES.

No. 928,701. Specification of Letters Patent. Patented July 20, 1909.

Application filed February 24, 1905. Serial No. 247,061.

To all whom it may concern:

Be it known that I, ADOLPH F. RIETZEL, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, (with post-office address Lynn, Massachusetts,) have invented certain new and useful Improvements in Uniting the Component Parts of Composite Sheet-Metal Structures, of which the following is a specification.

My invention relates to the manner of uniting or fastening two pieces of metal to one another and its object is more particularly to afford a substitute for the manner of uniting pieces of metal as heretofore practiced in the art of electric welding.

As applied to sheet metal manufactures the object is to afford a cheap and practical substitute for riveting and other methods of mechanically securing the two pieces of metal together. As applied to this branch of the metal working arts, the invention affords a means whereby articles of composite sheet metal manufacture may be made up by fastening the pieces of metal constituting the structure with a perfectly secure union and by a process that can be economically conducted.

Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots.

By the terms "weld" and "electric weld", as herein employed, I refer to that process of welding in which the metal is brought to plastic condition by passing an electric current from one to the other of two pieces where they are in contact and is welded while in such condition by the application of pressure, as contra-distinguished from a process of uniting metals, which is described in a patent to Bernardos, No. 363,320, dated May 17, 1887, and in which the union is effected by melting the metal by an arc and which is different from "welding" in the ordinary sense of the term as applied to metal manufactures, in that the metal is heated beyond the point of plasticity and pressure is not employed.

It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces. It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces. A weld formed according to my invention is distinguished however from such prior welds by the fact that the opposed surfaces are welded together in spots only, the heating electric current being localized or confined in any desired way to such spots so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together.

My invention is particularly valuable in fastening of pieces of sheet metal together because not only does it limit the amount of electric energy required very considerably as compared with the prior methods of union, but it also diminishes the liability to burning of the metal which is liable to occur when the attempt is made to form a union of two sheets of metal by an electric welding process over substantially the whole area of the meeting or opposed surfaces.

In carrying out my invention any desired number of spots of union may be employed, such number depending obviously upon the extent of the meeting surfaces which are to be fastened together and also upon the strength of the union desired.

In carrying out my invention the localization of the flow of heating electric current and of welding pressure to the desired spot or spots may be brought about in any desired way. One of the preferred ways is by providing between the meeting surfaces or portions of the pieces to be united suitable conducting projections or points at the spots of union, which projections or points carrying the heating electric current from one piece to the other are so located in the meeting surfaces and are so separated from one another that on the application of the weld-

ing pressure the welded union resulting will be localized in the area of the opposed surfaces and will be substantially coextensive in area with the restricted area of the path of the effective heating current. Various ways of providing such points or projections will occur to those skilled in the art.

The preferred method is to indent the metal from the side reverse to that on which the union is effected by a suitable tool, the projections thus formed affording points for the passage of the electric current. This method is preferable also because it permits the welding to be produced at a multiplicity of spots simultaneously through the application of pressure over the whole rear surface of the plate, the points or projections in that case serving not only to localize the flow of the heating current but also to localize the welding pressure.

In the preferred manner of carrying out my invention in the case of sheet metal manufacture I provide projections from the meeting surfaces of both pieces that are to be united. Said projections may also be provided by interposing between the two plane sheets small pieces of conducting material which act in the same manner when the sheets are brought together, as projections which localize the heating current and the pressure. It will be understood, however, that in the latter instance as in the former, these pieces are so small and are placed such a distance apart that on the application of welding pressure there will be no running of the welds into one another but that the final union will be in spots only leaving well-defined areas on the meeting surfaces, in which the surfaces either lie in contact or separated from one another by a very thin space.

From the foregoing it will be seen that my invention is distinguished from prior methods of welding pieces of metal together in that it may be very cheaply practiced, because no attempt is made to weld over the whole of the opposed surfaces of the welded pieces; but on the contrary the union is at a spot or spots only which in ordinary cases will afford as strong a union as would be produced by the riveting of the pieces.

The invention further has the advantage that not nearly so much electric energy is required as is necessary when the electrically welded union extends over the whole area of the opposed surfaces. Moreover, the danger of burning when the attempt is made to weld two sheets of metal together by a lap weld is largely eliminated.

In the accompanying drawings Figures 1, 2, 3, 4 and 5 illustrate some of the ways in which the pieces of metal to be united may be prepared for the welding according to my invention. Figs. 6, 7, 8, and 9 show modifications in the form and disposition of the contact projections which result in the spots of electrically welded union. Fig. 10 shows the assembling of three plates together for welding according to my invention.

In the various figures of the drawing the invention is illustrated as carried out with two sheets of metal B. B'. In Fig. 1, plate B'. only is provided with the distinct or isolated spots (c) or projections for the flow of the electric current, to the plate B, which spots or points may be formed by indenting the plate with a suitable tool. The spots are located so far from one another that on the application of pressure coincidently with the flow of electric current from one plate to the other there will be a number of distinct areas or spots of electrically welded union of the plates separated by well-defined areas on the meeting surfaces in which no union takes place. The resultant is however a fastening of the plates together securely and which is practically as effective as if the attempt were made to form a welded union over the entire areas of the meeting surfaces. Obviously, the greater the distance between the spots the lesser the number that would be used and hence the lesser the consumption of energy in effecting the weld. This is of considerable importance where the meeting areas are large or where a considerable amount of work has to be done. The welding pressure is conveniently applied by conducting-blocks or electrodes, A, A', between which the two pieces B, B', are assembled. These electrodes, A, A', furnish the heating current while applying the pressure, the localization of the pressure in the spots being brought about in this instance by the pointing of the surfaces at point c.

In Fig. 2 both plates are provided with projections the points of which engage with one another, the pointing being produced by indenting the metal sheets from the rear.

Fig. 3 illustrates the localization of the welding by casting projections upon one of the sheets and Fig. 4 by casting projections on both pieces. The localization of the welding in spots might be effected as illustrated in Fig. 5 by interposing small pieces of metal at the spot or spots of desired union, these pieces operating when the plates are brought together in the same way as the projections before referred to. The number and size of the pieces and their distance apart is in this case, as before, so chosen that the application of pressure together with the flow of heating current from one plate to the other will result in a union of the two pieces over their opposed surfaces in spots only thereon.

Fig. 6 shows how the spots might be disposed to fasten the pieces together in distinct spots around their edges.

As shown in Figs. 7 and 8 the projections, instead of being round, might be somewhat elongated and irregularly or symmetrically arranged.

Fig. 9 shows round and somewhat elongated projections combined.

In all these instances however, the union over the surfaces of the plates is confined to spots or areas which are of comparatively small extent as compared with the total area of the meeting surfaces. As will be obvious, the form and disposition of the points or projections of initial contact for flow of the electric current and localization of the pressure may be greatly varied without departing from my invention.

Fig. 10 illustrates the welding of three plates of sheets together when superposed.

My invention is especially useful in the manufacture of articles from sheet metal which are stamped out to different forms, and which have heretofore had their component portions united by riveting or other purely mechanical expedient which is not only expensive but requires generally special tools and results in many cases in an insecure union. When the invention is employed in its preferred form or manner of practice in the field of sheet metal manufacture all that is necessary is to provide the contact spots or projections as already described and then to assemble the pieces in an electric welding machine and weld them together as already set forth.

The product of the foregoing process is readily distinguishable from that produced by melting down the metal of the pieces, from the back at spots as proposed in the before mentioned patent of Bernardos in that there is no substantial alteration of condition of the metal back of the welds appearing as a burning, roughening or disintegration of the material by the very great heat of the electric arc employed for melting down the metal, and by the further fact that the unions themselves in the material of the juxtaposed or opposite faces have the characteristics of a true weld produced by bringing the metal to welding temperature only and applying pressure, so that the pieces are solidly and firmly united and cannot be readily torn apart as they could be if the metal at the spots has been melted down under the high temperature of the electric arc.

The product in the form of sheet metal is further particularly useful for sheet metal ware since the outer or exposed surface of the metal will have the smooth and practically unaltered finish of sheet metal and said surface will not be substantially marred when the process is properly conducted, excepting for the presence of such infrequent small depressions as might remain from the previous indentation of the metal from the back when, as hereinbefore described, an indenting of the metal may be resorted to.

The product in sheet metal also possesses the advantage that the spots of welding when located within the edges of the meeting surfaces will not show. The product is also superior to that produced by riveting of the plates in that there are no rivet heads to mar the finish of the back or outer surfaces of the metal.

What I claim as my invention is:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

7. The method of welding two pieces of metal together, consisting in superposing said pieces with their surfaces at which the union is to take place superposed or pre-

sented to one another, pressing the pieces together, and passing a heating electric current from one to the other while localizing the heating current simultaneously in a number of distinct or separate spots of limited area, separated from one another sufficiently to secure a union of the pieces in a number of corresponding distinct spots surrounded by and separated from one another by distinct areas in which no union exists.

8. The method of uniting two pieces of metal, consisting in providing between their meeting surfaces a number of projections, spaced apart as described, pressing the pieces together and passing an electric current through said projections while confining the welding area of such current to said projections so as to leave distinct areas around spots in which no welding shall be produced.

9. The method of fastening two plates of metal together at a multiplicity of distinct or separate points of welded union, consisting in providing between them a number of isolated contact spots adapted to pass an electric current from one to the other but so separated that the electric welds will be separated from one another by unwelded areas, passing a heating electric current through such spots simultaneously and applying pressure as and for the purpose described.

10. The herein described method of electrically welding two plates or sheets of metal of any gage together by distinct spots of union disposed over their plane surfaces, consisting in providing a multiplicity of electrical contact spots coincident with the separated spots of union and disposed at such distances apart that there will be well-defined areas between spots through which the electric current will not flow, passing electric current from one plate to the other through said contact spots simultaneously and applying pressure as and for the purpose described.

11. The method of fastening two sheets of metal together, consisting in providing between them a number of isolated contact spots for the passage of the electric welding current, said spots being adapted to initially hold the plates apart and being separated from one another a sufficient distance to confine the welding to distinct areas or isolated spots, passing a heating electric current through a number of said contact spots simultaneously and pressing the plates together as and for the purpose described.

12. The method of fastening two plates of metal together, consisting in furnishing a surface of said plates with a number of projecting contact spots for the passage of welding electric current and disposed at such distances apart that on the application of pressure the welds will not run into one another, superposing said plates, passing a heating electric current from one to the other over said separated spots and applying the pressure to produce a spot-welding of the plates to one another as and for the purpose described.

13. The herein described method of fastening two pieces of metal together by providing each plate with a number of projecting contact spots on its plane surface disposed at such distances apart that the unions will not run into one another but will, nevertheless, firmly hold the plates together, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other through the spots and simultaneously applying pressure thus uniting the plates at a number of distinct points of welded union.

14. The method of uniting two sheets of metal face to face, consisting in indenting the material, superposing the plates with the points of the indentations engaged, passing an electric current from one plate to the other through said points simultaneously, and applying pressure while confining the area of heating to welding temperature to a circumscribed area or spot entirely surrounded by areas unheated to welding temperature to unite the pieces in a distinct spot or spots of small extent in the whole area of the opposed faces.

15. The herein described method of fastening two plates together at a multiplicity of distinct mechanically separated points of welded union, consisting in indenting each plate to form a number of projecting contact spots on the plane surfaces which are to abut, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other thereby forming a number of distinct zones or points of heated metal, heated to welding temperature, and applying pressure to complete the union of plates by a number of mechanically distinct unions.

16. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

20. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

Signed at Lynn in the county of Essex and State of Mass. this 7th day of Feb. A. D. 1905.

UNITED STATES PATENT OFFICE,

In re Interference:

JOHANN HARMATTA

vs.

SEBASTIAN ZIANI DE FERRANTI.

No. 36,709.

MOTION TO STRIKE OUT TESTIMONY.

NOW COMES JOHANN HARMATTA, by his attorneys, and moves to strike out the following portions of the testimony taken

on behalf of De Ferranti on the 10th and 11th days of November 1916, to wit:

All of Q. 6 referring to the Rietzel patent and embraced in the sentence beginning "In this connection you might also consider the disclosure in patent 928,701, Reitzel, July 20th 1909" and ending with the words "disclosure in this Rietzel patent."

All portions of the answer 6 referring to the Rietzel patent and beginning on page 4 of the deposition as filed with the words "Now referring to the Rietzel patent", down to the end of the answer on page 15.

The final sentence ot answer to Q. 7 reading "In point of fact the Rietzel patent" etc.

The offer in evidence of the Rietzel patent if the same is to be taken as a part of the deposition of the witness and as evidence in rebuttal.

All of the answer to X-Q. 44 referring to the Standard Handbook for Electrical Engineers excepting the first sentence of said answer.

The grounds of this motion are those stated by counsel for De Ferranti on the record and upon the general ground that the testimony and portions of the record embraced in the above motion are incompetent as rebuttal testimony taken for De Ferranti.

We also move for a stay of proceedings pending the final determination of this Motion.

JOHANN HARMATTA.

Very respectfully,

THOMAS EWING,
Commissioner of Patents.

6—1652.

This case is before me on motion by Harmatta, filed Nov. 25, 1916, to strike out certain of the testimony taken by de Ferranti in rebuttal.

It is quite difficult to satisfactorily pass upon matters of this kind without reading the entire record. There is apparently no sufficient reason why this should be done prior to the final hearing.

Action upon this motion is therefore hereby deferred until the case is presented at final hearing on its merits.

H. E. STAUFFER,
Examiner of Interferences.

DE FERRANTI

vs.

HARMATTA.

INTERFERENCE No. 36,709.

It is hereby stipulated and agreed that the time for closing the rebuttal evidence by De Ferranti be extended thirty days from the time now set. A cablegram has just been received by the attorneys for De Ferranti to the effect that their British correspondents are pressing to secure the evidence which they consider necessary and vital to this case, but that they are delayed by war conditons. It is believed that this is a sufficient reason for the granting of the extension.

INTERFERENCE No. 36,709.

City of Washington, District of Columbia, ss:

James M. Spear, being duly sworn, deposes and says that he is a member of the firm of Spear, Middleton, Donaldson & Spear, Attorneys for De Ferranti, party to the above entitled interference and has been conversant with the progress of said interference; that promptly after the conclusion of the taking of testimony on behalf of Harmatta deponent's firm proceeded with the matter of the taking of rebuttal evidence on behalf of De Ferranti and to this end deponent's firm corresponded with the English attorneys of Ferranti, from whom the U. S. application was received; that after unavoidable delays and at the earliest possible moment testimony of Mr. Frank L. Dyer, as an expert, was taken on behalf of Ferranti; that it is deemed essential to the interests of De Ferranti that his testimony as inventor, the testimony of Mr. Gerald Stoney, for many years chief assistant to Hon. Charles Parsons, the famous steam turbine inventor, and that of Mr. M. Atkinson Adam, who prepared the original De Ferranti English application as well as the U. S., be taken also in rebuttal; that the testimony,

which these parties will give, will in deponent's opinion be material and necessary to the interests of De Ferranti; that deponent has been informed and believes that it is absolutely impossible for these parties to come to this country to testify; due to war conditions and the fact that they are all engaged in important governmental matters connected with the war; that deponent's firm has been consistently diligent in its efforts to obtain the necessary data from said parties to enable it to prepare the necessary interrogatories to accompany a motion to take testimony abroad; that deponent's firm has only this day received from its English correspondents information for the preparation of interrogatories for the deposition of said M. Atkinson Adam and is informed by the letter accompanying said information that deponent's English correspondent expected to mail in a few days thereafter information for the preparation of interrogatories for the depositions of the said parties De Ferranti, and Stoney; that deponent's firm is informed by its English correspondents and deponent, therefore, believes that it has been absolutely impossible to get this material earlier, due to the fact that said parties Adams, De Ferranti and Stoney, have, as heretofore stated, been engaged in important governmental and munition work, which absolutely precluded their giving proper attention to their private business; that as heretofore stated it is believed that the evidence to be taken is important and material; and that this motion is made in good faith and not for the purposes of delay.

IN THE UNITED STATES PATENT OFFICE.

S. Z. DE FERRANTI

vs.

JOHANN HARMATTA.

INTERFERENCE No. 36,709.

MOTION.

And now comes De Ferranti, by his attorneys, and moves for permission to take testimony abroad before the U. S. Consul-General in London, England, of the following parties, to wit: Sebastian Z. De Ferranti, Gerald Stoney, and M. Atkinson Adam, all of London, England.

It is expected that these witnesses will each and all rebut the testimony of Herman Lemp, and James H. Gravell, expert witnesses produced on behalf of Harmatta; and specifically that they will establish that the disclosure of the De Ferranti provisional application in Great Britain is a disclosure of spot welding and not merely butt welding as contended by the witnesses produced on behalf of Harmatta, and that they will corroborate the testimony of Frank L. Dyer heretofore taken on behalf of De Ferranti, and that, therefore, they will establish the fact that the disclosure in the said British provisional specification fully supports the issues of the interference, the contrary to which has been alleged by said witnesses produced on behalf of Harmatta.

It is further expected that the witnesses De Ferranti and Adam will testify that De Ferranti produced a weld between the blade and carrier which did not extend over the whole surface of the turbine blade, but on the contrary as welded at isolated spots only of their juxtaposed surfaces.

It is further expected that the witnesses will clearly differentiate the disclosure in the De Ferranti English Provisional specification from the prior art discussed by the witnesses produced on behalf of Harmatta and refute the assertions made by said witnesses Lemp and Gravell as to the identity of such disclosure of De Ferranti with the prior art.

It is further expected that the witness Stoney will produce sketches made by him from the disclosure of the De Ferranti Provisional specification only, and will explain how and why this is spot welding as distinguished from butt welding.

It is further expected that the witnesses each and all will testify that the welding of the blades in isolated spots only of their juxtaposed surfaces is not inconsistent with the requirements of "due mechanical strength" mentioned in said Provisional specification, as asserted by the witnesses produced on behalf of Harmatta and will give their reasons therefor.

Respectfully,

S. Z. De Ferranti.

BEFORE THE EXAMINER OF INTERFERENCES.

DE FERRANTI

vs.

HARMATTA.

INTERFERENCE No. 36,709.

BRIEF FOR HARMATTA IN OPPOSITION TO THE MOTION OF DE FERRANTI FOR LEAVE TO TAKE TESTIMONY ABROAD.

This is a motion brought by de Ferranti under Rule 158 for leave to take testimony in London, England.

The showing of the accompanying motion is insufficient to warrant the granting of the same. As to the requirements specified in Clause (a) of the Rule the motion sets forth no sufficient grounds on which is based the belief that the witnesses will testify in the manner set forth in the motion. All that is said is that the deponent Spear believes the witnesses will so testify by reason of information to this effect received by his firm from said parties.

As to the requirements of Clause (b) of the Rule, there is no showing of facts from which it can be concluded that the testimony cannot be taken in this country at all or that it cannot be taken here without hardship and injury to the moving party greatly exceeding that to which the party Harmatta would be exposed by the taking of such testimony abroad. In place of such showing of facts the motion paper substitutes a mere statement of James M. Spear that he believes that the parties whose testimony it is desired to take cannot leave England. As to the matter of comparative hardship no showing seems to be made whatever.

Upon the general merits of the motion we call attention to the fact that the evidence which it is desired to take is simply in the nature of expert or opinion evidence of persons residing abroad to be adduced in rebuttal of expert or opinion evidence given on behalf of Harmatta in this country and by witnesses residing in this country.

The aid of Rule 158 is thus invoked by de Ferranti for a purpose entirely foreign to the intent of said Rule. This Rule was the outgrowth of the decision of Commissioner Paine in the case of Laurer vs. Crowell, et al., C. D. 1879, page 177. That case and many subsequent cases, among them Parkin & Wright vs. Jenness, C. D. 1893, page 64; Smith vs. Barger, C. D. 1875, page 1; Green

vs. Hall vs. Siemens vs. Fields, C. D. 1889, page 110, show clearly that the only purpose of this Rule was to permit testimony to be taken abroad as to foreign publications or patents by which a date of invention under the Patent Statutes could be established, or for the purpose of showing some one of the contestants is not the original inventor. It was never intended by this Rule to put it into the power of a contestant in the United States Patent Office to go abroad for expert or opinion evidence, certainly not in the case of so widely known an art as that involved in the present controversy and, under the protection of said Rule, to subject his opponent to the recognized hardship and disadvantage of having to meet the case prepared in advance abroad and to cross-examine witnesses on a case so prepared under the disadvantages of the procedure now invoked.

It is unbelievable that witnesses competent to give expert and opinion evidence upon the subjects of electric welding and turbine construction do not exist in this country and there is no more reason for taking expert and opinion evidence abroad in this case than there would be in any of the numerous cases coming before the Patent Office for adjudication and wherein evidence of that nature can be properly used. To permit the Rule 158 to be used for any such purpose as is here proposed would open the door to contestants to gravely harrass opponents and should not be permitted in any case and certainly not in a case such as the present and upon any such showing as is herein made.

As to the particular witnesses which it is proposed to call and the particular nature of their testimony, it may be said that what the writer of the provisional specification may think that he meant or may now say that he meant is not competent or material evidence to establish what the specification actually means as a publication and disclosure to the ordinary reader of the same. Anything that the writer might say as to the meaning of the specification to a third party reading the same is no more competent or material than would be the evidence of anyone of thousands of specification writers in this country.

Indeed the testimony of the attorney would be of much less weight and importance than that of some other person because his testimony would be tinged by the fact that he wrote the specification and may have had certain ideas in mind which were not expressed in a way to disclose the thought.

That de Ferranti produced a weld in the manner claimed in the motion would not be competent or material testimony as it would be simply evidence of what the inventor did abroad and would not support the claim of disclosure by patent or publication. The remaining testimony which it is proposed to take is clearly in the nature of expert or opinion evidence which could just as well be taken in this country.

As to Mr. de Ferranti, any testimony that he may give as to the nature of the disclosure made by the publication can borrow no effect or value from the fact that he is the alleged inventor.

As to Mr. Adam, the fact that he was attorney for Mr. de Ferranti similarly can give no weight or effect to testimony as to the nature of the disclosure beyond what would attach to the testimony of any other patent attorney and as before stated would be even of less weight. It does not appear even that Mr. Adam is possessed of special expert knowledge but even if he were expert in the art to which the invention relates, that fact establishes no warrant for the taking of testimony of the nature proposed abroad.

The expert opinion evidence which it is desired to produce through Mr. Stoney is of the same nature which anyone of numerous experts in this country would be able to give did the facts warrant it.

The rule permitting testimony to be taken in foreign countries was only framed to meet exceptional cases in which it was necessary to prove the facts of invention by witnesses residing abroad and with whom sole knowledge of the facts necessarily lay. It was not framed to permit a party to an interference to select witnesses living abroad in preferenc to witnesses living in this country to give expert opinion evidence and then to say that because the witnesses live abroad he should be premitted to produce their evidence under the Rule 158 in preference to evidence of the same nature which could be as well obtained in this country.

Respectfully submitted,
TOWNSEND & DECKER,
Attorneys for Harmatta.

U. S. Patent Office.

UNITED STATES PATENT OFFICE.

BEFORE THE EXAMINER OF INTERFERENCES.

DE FERRANTI

vs.

HARMATTA.

INTERFERENCE No. 36,709.

MOTION ON BEHALF OF DE FERRANTI FOR EXTENSION OF TIME TO TAKE REBUTTAL TESTIMONY.

BRIEF FOR HARMATTA.

It appears from the affidavit of James M. Spear attached to the motion papers that further time is desired by de Ferranti in order

that testimony may be taken abroad. The motion seems to proceed upon the assumption that leave has been or will be granted pursuant to Rule 158 of the Rules of Practice permitting testimony to be taken in foreign countries upon the showing the precise character of which is fully set forth in the Rule. No such showing and motion have been made and granted and until the granting of such a motion the filing of interrogatories is not permitted. As stated in Raffard vs. de Ferranti, 60 O. G. 439:

> "Rule 158, under which a suitor before this Office may secure and introduce evidence taken in foreign countries, is precise in its terms and points out a definite and specific mode of procedure. It directs that after a petitioner has presented his motion and secured permission to take such testimony interrogatories must be filed within a limited time, and cross-interrogatories, also, if the opposing party shall elect to question the witness. This is the natural and prescribed way of proceeding under the rule; but it is definitely provided that this procedure may be waived to the extent of permitting an oral examination *by stipulation of the parties*. There can be no doubt as to the meaning of this, and there is no question that a party seeking the protection of the rule is entitled to all the privileges which it guarantees in terms. Plainly, nothing short of the mutual assent of all the interested parties can avoid its strict letter."

In view of the status of the present case and the long time that has elapsed since Harmatta completed his testimony, it is submitted that further time should be granted to de Ferranti only for the express purpose of permitting him to bring a motion under Rule 158. If, and only when such motion is granted can the motion for further time to take testimony be properly entertained. It is submitted that any extension of Ferranti's time should be made conditional upon his promptly bringing and prosecuting a motion under Rule 158.

Respectfully,
TOWNSEND & DECKER,
Attorneys for Harmatta.

BEFORE THE EXAMINER OF INTERFERENCES.

INTERFERENCE No. 36,709.

DE FERRANTI

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

THOMAS EWING,

6—1652 *Commissioner of Patents.*

This case is before me for consideration of the following motions by De Ferranti:

1. A motion for permission to take testimony abroad, filed April 17, 1917.

2. A motion for an extension of time in which to take rebuttal testimony, filed April 16, 1917.

Motion to Take Testimony Abroad: The testimony which the moving party intends to take, should this motion be granted, is said to consist entirely of the depositions of De Ferranti himself, the patent attorney who prepared the specification for his British application, and a single other witness, expert in the art to which the invention relates. The avowed purpose of all this testimony is to explain the meaning or intended meaning of the disclosure in the provisional specification forming a part of the British patent relied upon by De Ferranti as a constructive reduction to practice of the invention and to demonstrate how said disclosure differs from the prior art and corresponds to the process defined in the issue herein. By this means De Ferranti seeks to rebut attacks upon his British patent by certain experts who, testifying on behalf of his opponent, expressed the opinion that the De Ferranti British provisional specification relates to a method of welding distinctly different from that in issue, and which method was old in the art at the time the provisional specification was filed.

The necessity for taking the testimony of the proposed witnesses is not apparent. Statements by De Ferranti or his former attorney as to what De Ferranti intended to disclose in his provisional specification would, of course, have no value. The specification must speak for itself. Nor would it seem to be necessary to go abroad for expert testimony which presumably could be obtained in this country. As a matter of fact De Ferranti has already taken and filed the testimony of one expert covering the very matters concerning which he desires to take further expert testimony abroad. Testimony of the sort proposed is, moreover, of doubtful value in the determination of the question to which it is directed, namely, the sufficiency of the provisional specification of De Ferranti's British patent as a disclosure of the invention. The testimony of experts as to the meaning of the issue or in explanation of the contents of an application is ordinarily not desired or permitted (Ricketts vs. Ambruster & Beck, 144 O. G., 276; Von Keller vs. Hayden vs. Kruh vs. Jackson, 173 O. G., 285; Cooper vs. Downing, 222 O. G., 727). Whether or not the aforesaid provisional specification discloses the invention can apparently be determined from a consideration of the specification itself, without the aid of testimony. If De Ferranti considers that the testimony taken by Harmatta is improper, his course would seem to be to attempt to secure its suppression. Or, if he prefers to let such testimony stand and to endeavor to rebut it, his efforts in that direction would not apparently be prejudiced or unduly restricted by confining his rebuttal testimony to the depositions of experts in this country, of which he has in fact already availed himself. The showing does not require or justify the taking of testimony abroad, as proposed in the motion.

Motion to Extend Time: This motion asks that De Ferranti's rebuttal time be extended to cover the taking of rebuttal testimony abroad, as set out in his other motion. The showing in support of the extension relates only to the additional time necessary for the taking of such testimony. Inasmuch as De Ferranti will not be permitted to take testimony abroad, no reason is advanced that would render an extension of time necessary.

The motion to take testimony abroad is denied.

The motion to extend time for rebuttal testimony is denied.

Limit of appeal from denial of motion to take testimony: May 7, 1917.

The taking of testimony is suspended.

S. Z. DE FERRANTI

vs.

HARMATTA.

INTERFERENCE No. 36,709.

APPEAL.

Appeal is hereby taken to the Honorable Commissioner of Patents from the decision of the Examiner of Interferences denying the motion for permission to take testimony abroad and for an extension of time in which to take rebuttal testimony. In support of the motion it is alleged that the Examiner erred in holding that the necessity for taking the testimony of the proposed witnesses is not apparent; that he erred in holding that statements by De Ferranti or his former Attorney would not have any value; that he erred in not holding that in view of the fact that this invention was made abroad and the further fact that the affidavit supporting the motion shows the proposed witnesses to have had long experience and special knowledge in this particular art would make their evidence material and important and of a character that would not be procured in this country; that he erred in not granting the motion for permission to take testimony abroad and finally that he erred in not granting an extension of time in which to take such rebuttal testimony.

Respectfully,
S. Z. DE FERRANTI.

SIR:

The case of

DE FERRANTI

vs.

HARMATTA.

APPEAL ON MOTION.

Intf. No. 36,709 will be heard by the Commissioner on the 25th day of May, 1917.

The hearings will commence at ten o'clock, and as soon as the argument in one case is concluded the succeeding case will be taken up.

If any party, or his attorney, shall not appear when the case is called, his right to an oral hearing will be regarded as waived.

The time allowed for arguments is as follows:

Ex parte cases, thirty minutes;

Motions, thirty minutes, each side;

Interference appeals, final hearing, one hour each side.

By special leave, obtained before the argument is commenced, the time may be extended.

The appellant shall have the right to open and conclude in interference cases, and in such case a full and fair opening must be made.

Briefs in interference appeals must be filed in accordance with the provisions of Rule 144.

Respectfully,
THOMAS EWING,
Commissioner of Patents.

Intf. No. 36,709. Paper No 93.

IN THE UNITED STATES PATENT OFFICE.

BEFORE THE COMMISSIONER OF PATENTS

ON APPEAL BY DE FERRANTI.

DE FERRANTI

vs.

HARMATTA.

INTERFERENCE NO. 36,709.

BRIEF FOR HARMATTA IN OPPOSITION.

De Ferranti's appeal is taken from the decision of the Examiner of Interferences rendered April 28th 1917 refusing to grant de Ferranti's motion filed April 17th 1917, under Rule 158, for leave to take testimony in London, England.

The brief filed by the party Harmatta in opposition to the grant of that motion and filed at the hearing before the Examiner of Interferences fully sets forth the party Harmatta's reasons as to why the motion should not be granted, said arguments being substantially reproduced herein.

The showing of the motion is insufficient to warrant the granting of the same. As to the requirements specified in Clause (a) of the Rule the motion sets forth no sufficient grounds on which is based the belief that the witnesses will testify in the manner set forth in the motion. All that is said is that the deponent Spear believes the witnesses will so testify by reason of information to this effect received by his firm from said parties.

As to the requirements of Clause (b) of the Rule, there is no showing of facts from which it can be concluded that the testimony cannot be taken in this country at all or that it cannot be taken here without hardship and injury to the moving party greatly exceeding that to which the party Harmatta would be exposed by the taking of such testimony abroad. In place of such showing of facts the motion paper substitutes a mere statement of James M. Spear that he believes that the parties whose testimony it is desired to take cannot leave England. As to the matter of comparative hardship no showing seems to be made whatever.

Upon the general merits of the motion we call attention to the fact that the evidence which it is desired to take is simply in the nature of expert or opinion evidence of persons residing abroad to be adduced in rebuttal of expert or opinion evidence given on behalf of Harmatta in this country and by witnesses residing in this country.

The aid of Rule 158 is thus invoked by de Ferranti for a purpose entirely foreign to the intent of said Rule. This Rule was the

outgrowth of the decision of Commissioner Paine in the case of Lauder vs. Crowell, et al., C. D. 1879, page 177. That case and many subsequent cases, among them Parkin & Wright vs. Jenness, C. D. 1893, page 64; Smith vs. Barker, C. D. 1875, page 1; Green vs. Hall vs. Siemens vs. Fields, C. D. 1889, page 110, show clearly that the only purpose of this Rule was to permit testimony to be taken abroad as to foreign publications or patents by which a date of invention under the Patent Statutes could be established, or for the purpose of showing some one of the contestants is not the original inventor. It was never intended by this Rule to put it into the power of a contestant in the United States Patent Office to go abroad for expert or opinion evidence, certainly not in the case of so widely known an art as that involved in the present controversy and, under the protection of said Rule, to subject his opponent to the recognized hardship and disadvantage of having to meet the case prepared in advance abroad and to cross-examine witnesses on a case so prepared under the disadvantages of the procedure now invoked.

It is unbelievable that witnesses to give expert and opinion evidence upon the subjects of electric welding and turbine construction do not exist in this country and there is no more reason for taking expert and opinion evidence abroad in this case than there would be in any of the numerous cases coming before the Patent Office for adjudication and wherein evidence of that nature can be properly used. To permit the Rule 158 to be used for any such purpose as is there proposed would open the door to contestants to gravely harrass opponents and should not be permitted in any case and clearly not in a case such as the present and upon any such showing as is herein made.

As to the particular witnesses which it is proposed to call and the particular nature of their testimony, it may be said that what the writer of the provisional specification may think that he meant or may now say that he meant is not competent or material evidence to establish what the specification actually means as a publication and disclosure to the ordinary reader of the same. Anything that the writer might say as to the meaning of the specification to a third party reading the same is no more competent or material than would be the evidence of anyone of thousands of specification writers in this country.

Indeed the testimony of the attorney would be of much less weight and importance than that of some other person because his testimony would be tinged by the fact that he wrote the specification and may have had certain ideas in mind which were not expressed in a way to disclose the thought.

That de Ferranti produced a weld in the manner claimed in the motion would not be competent or material testimony as it would be simply evidence of what the inventor did abroad and would not support the claim of disclosure by patent or publication. The remaining testimony which it is proposed to take is clearly in the na-

ture of expert or opinion evidence which could just as well be taken in this country.

As to Mr. de Ferranti, any testimony that he may give as to the nature of the disclosure made by the publication can borrow no effect or value from the fact that he is the alleged inventor.

As to Mr. Adam, the fact that he was attorney for Mr. de Ferranti similarly can give no weight or effect to testimony as to the nature of the disclosure beyond what would attach to the testimony of any other patent attorney and as before stated would be even of less weight. It does not appear even that Mr. Adam is possessed of special expert knowledge but even if he were expert in the art to which the invention relates, that fact establishes no warrant for the taking of testimony of the nature proposed abroad.

The expert opinion evidence which it is desired to produce through Mr. Stoney is of the same nature which anyone of numerous experts in this country would be able to give did the facts warrant it.

The rule permitting testimony to be taken in foreign countries was only framed to meet exceptional cases in which it was necessary to prove the facts of invention by witnesses residing abroad and with whom sole knowledge of the facts necessarily lay. It was not framed to permit a party to an interference to select witnesses living abroad in preference to witnesses living in this country to give expert opinion evidence and then to say that because the witnesses live abroad he should be permitted to produce their evidenc under the Rule 158 in preference to evidence of the same nature which could be as well obtained in this country.

It is therefore contended that the Examiner was right in his decision in denying the motion and that the present appeal should also be denied.

Respectfully submitted,

TOWNSEND & DECKER,
Attorneys for Harmatta.

New York, May 24th, 1917.

Recorded Vol. 123, p. 97. Intf. No. 36,709. Paper No. 94.
Hearing: May 25, 1917. SET

IN THE UNITED STATES PATENT OFFICE.

DE FERRANTI

vs.

HARMATTA.

PATENT INTERFERENCE No. 36,709.

APPEAL ON MOTION.

ELECTRIC WELDING.

Application of Sebastian Z. de Ferranti filed Dec. 29, 1911, No. 668,464, division of application filed May 14, 1904.

712 Defendant's Exhibit No. 33.

Patent granted Johann Harmatta Dec. 3, 1912, No. 1,046,066, on application filed Dec. 3, 1903.

MESSRS. SPEAR, MIDDLETON, DONALDSON & SPEAR, for de Ferranti.

MESSRS. TOWNSEND & DECKER for Harmatta.

This is an appeal by de Ferranti from the decision of the examiner of interferences denying his motion to take testimony abroad.

It appears that de Ferranti relies upon a British application and that in his testimony in chief a copy of this application was introduced in evidence, and that thereafter testimony was taken on behalf of Harmatta for the purpose of showing that the invention in issue is not disclosed in the British provision specification. Permission was then sought to take the testimony of de Ferranti, Stoney, and Adam, it being stated that it was expected to prove by de Ferranti and Adam that de Ferranti had actually produced a weld between the blade and the carrier which did not extend over the whole surface of the turbine blade, and that the welding of the blades in isolated spots is not inconsistent with the requirement of "due mechanical strength" mentioned in the provisional specification, and that the witness Stoney would produce sketches made by him from the disclosure of the de Ferranti provisional specification only, and explain how and why this is spot welding as distinguished from blade welding.

At the hearing on this appeal the motion was withdrawn in so far as it asked to take the testimony of Adam, who is the English attorney to whom de Ferranti's original disclosure is said to have been made.

No error is found in the holding of the examiner of interferences denying the motion. Any work done by de Ferranti in England is immaterial to the question of priority. The question for consideration is what the original specification discloses. It is not seen that the fact that de Ferrant may have made welds in a certain way in any way establishes that that method is disclosed in the provisional specification. De Ferranti has already introduced the testimony of an expert in support of his contention that the invention is disclosed in the provisional specification, and it would seem that if any other further expert testimony was necessary, it could have been obtained from an expert in this country.

The decision of the examiner of interferences is affirmed.

R. F. WHITEHEAD,
First Assistant Commissioner.

In re: Interference

SEBASTIAN ZIANI DE FERRANTI

vs.

JOHANN HARMATTA.

No. 36,709.

MOTION FOR JUDGMENT.

NOW COMES JOHANN HARMATTA by his duly authorized attorneys and moves that judgment on the ex parte records of the parties hereto and in view of the Rietzel patent No. 928,701,

one Rietzel, No. 928,701, and the decisions of the Court of Appeals of the District of Columbia in *in re* Fritts, 227, O. G., 742, and Rowntree vs. Sloan, 227 O. G., 744.

Reference to the file shows that the final hearing on the merits is now set for September 7, 1917. All the testimony has been taken and the printed records of the respective parties are on file. It would in my judgment be clearly better to have this question raised at the time fixed for the final hearing on the merits, at which time all grounds for decision may be properly presented and discussed.

The motion is denied with the right to renew the same at the final hearing.

PETITION.

To the Commissioner of Patents;

Your Petitioner Adolph F. Rietzel a citizen of the United States and a resident of Lynn in the County of Essex and State of Massachusetts with P. O. address, Lynn, Mass. prays that Letters Patent may be granted to him for the Method of Electric Welding set forth in the annexed specification; and he hereby appoints Henry C. Townsend and Delbert H. Decker, constituting the firm of Townsend & Decker, of the City of New York, ~~5 Beekman Street (Temple Court)~~ 141 Broadway, his attorneys with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to receive the patent, and to transact all business in the Patent Office connected therewith.

Adolph F. Rietzel

SPECIFICATION.

To all whom it may concern:

Be it known that I, Adolph F. Rietzel a citizen of the United States and a resident of Lynn in the County of Essex and State of Massachusetts with P. O. address, Lynn, Mass. have invented certain new and useful Improvement in ~~Method of Electric~~ Welding Uniting the Component Parts of Composite Sheet Metal Structures of which the following is a specification:

per Sub. Spec.

My invention relates to a method of forming an electrically welded union between the plane surface of a piece of metal and another piece of metal and is especially useful in uniting two plates or sheets of metal at their plane surfaces.

One of the special objects of the invention is to provide a method whereby a sheet of metal, especially in the thinner gages, may be united on its plane surface to another sheet or to any other piece of metal. For the sake of illustration, however, the process will be described as carried out in uniting two sheets or plates to one another for which purpose the invention is particularly useful. It is to be understood, however, that I do not limit myself to the process as applied to sheet or plate metal or to uniting two plates or sheets with one another, since the invention is also applicable to forming a welded union with a plane surface or contact surface of considerable area in a piece of metal of any form.

It is not practicable by the present process of electric welding to weld together two plates or sheets of metal on their plane surfaces, on account of the large area of surface contact between them, when laid one upon the other, which allows the welding current to pass without bringing them up to a welding heat.

My present invention consists essentially in providing over the surface to be welded, a number of contact spots or points through which the welding current is passed in multiple, and applying pressure in proper way to form a number of distinct electric welds or spots of union over said surface.

These contact spots act to localize the current and the heating to a welding temperature and may be provided either by casting, punching or indenting

the metal of the plane surface with which the welded union is to be made, or otherwise forming the same so as to provide thereon a multiplicity of isolated projections, or said contact spots may be provided by disposing a number of small pieces of metal over said surface, which pieces become united with said surface and with the opposite piece or pieces of metal in the welding process.

Figures 1, 2, 3, 4 and 5 show pieces of metal of different forms interposed between the electrodes of an electric welding machine; figures 6, 7, 8 and 9 show modifications in the form and disposition of the isolated projections.

Fig. 10 shows 3 plates assembled for welding together.

rased
er Sub.Spec.
ct. 23. '06

Referring to figures 1, 2, 3, 4 and 5, the electrodes of an electric welding machine are indicated at A'. These electrodes, as usual in the art, supply heating current to the work interposed between them, and also preferably serve as the means through which welding pressure may be applied to the work while heated to welding temperature. In Fig. 1, piece B' is a plate or sheet of metal to be welded at its plane surface to an opposite plate or sheet B. In this figure the plate B' has a number of isolated contact spots c, which may be formed by indenting the plate and which projections engage directly with the opposite plate B.

In Fig. 2 both plates have projections which engage with one another, although, and as indicated in Fig. 10, each of the contact spots or projections c upon one plate might engage with the plane surface of the opposite plate.

In the operation of forming the weld, current is passed from one plate or piece to the other through the contact spots or projections c, raising the metal to welding temperature at such points, and the application of welding pressure in the usual manner forms spots of welded union

coincident with such points or projections and which firmly unite the pieces together. The contact points, spots or projections might be formed on either or both surfaces by casting the projections thereon which modification is indicated in Figures 3 and 4 wherein the pieces B B' are supposed to be cast metal plates or pieces.

In Fig. 1 and 2 the plates are supposed to be of sheet metal. These plates or projections may be formed, however, in any desired way upon the surface withwhich the welded union is to be made. Instead of providing contact spots consisting of projections from the plane surfaces themselves, they may be provided by interposing separate pieces of metal, c', as indicated in Fig. 5, which are disposed in any desired number, according to the number of points of union desired, over the plane surface with which the welded union is to be formed. These different spots or projections may take any desired form or be disposed in any desired relation to one another and to the boundaries of the surface with which the welded union is to be made.

As shown in Fig. 6 they may be rounded projections disposed near the edges of the plate or they may be somewhat elongated projections as shown in Fig. 7 and 8 and symmetrically or irregularly arranged as shown; as shown in Fig. 9, they may be a combination of round and elongated projections.

As will be obvious their form and disposition may be greatly varied, and as already stated, the manner of producing them is capable of indefinite variation.

Fig. 10 illustrates the welding of 3 plates or sheets together. The number can be extended indefinitely, and while ordinarily only two pieces would be welded at a time, more may be welded provided the current is sufficient.

My invention is of special utility in the manufacture

of articles from sheet metal which are stamped out to different forms, and which heretofore have been joined in a mechanical way requiring expensive dies and tools to produce the finished article. When my invention is employed in this field of manufacture, all that is necessary in order to provide for the union of the pieces is to form or provide the spots or projections in any desired way or in any convenient form on the surface to be united either by punching, indenting or otherwise forming them up or by providing isolated metal pieces as already described, and then to assemble the pieces to be united in an electric welding machine and weld them together as already described.

In some cases it may be sufficient to provide a single projection or spot if the same be sufficiently elongated, which will act, as it were, to localize the heating and welding.

What I claim as my invention is:-

1. The herein described method of welding a piece of metal at a plane surface thereof, consisting in providing a multiplicity of contact spots over said surface, passing a heating electric current over said spots simultaneously, and applying pressure to form a multiplicity of distinct electric welds over said plane surface.

2. The herein described method of welding sheets or plates of metal together on their plane surfaces, consisting in providing a multiplicity of contact points or spots between said surfaces, passing a heating electric current from one plate to the other through said points in multiple and applying pressure in a direction to form a number of points of welded union between said plates and sheets.

3. The herein described method of uniting plates sheets or other metal objects on their plane surfaces, consisting in providing such surface with a multiplicity of contact points or projections, passing a welding current through said projections in multiple and applying pressure to form a number of welds simultaneously at said points.

4. The herein described method of uniting a sheet of metal with another piece of metal consisting in indenting the sheet to form one or more projections from a plane surface thereof, passing a heating electric current through sheet and said projection or projections, and applying pressure to form one or more spots of welded union on such surface.

5. The herein described method of welding two plates or sheets of metal together consisting in indenting the material to form a number of projections from a plane surface thereof heating said projections to a welding temperature simultaneously and applying pressure in a direction perpendicular to said

plane surface to form a number of spots of welded union thereon.

6. The herein described method of welding two plates or sheets of metal together consisting in indenting the material to form a contact spot or spots on a plane surface thereof, superposing said plates or sheets, passing an electric current from one to the other through said contact spots and applying pressure to form a point or points of welded union at said spot or spots.

7. The herein described method of welding two plates or sheets of metal together, consisting in indenting each plate to form a projecting contact spot or spots on a plane surface of each plate, superposing said plates with the projecting spot or spots in engagement with one another, passing a heating electric current from one plate to the other and applying pressure to form a welded union between the plates at said spot or spots.

8. The herein described method of electrically welding a piece of metal at a plane surface thereof consisting in providing such plane surface with a current localizing projection, passing a heating current through such projection and applying pressure to unite said piece with another piece by a welded union coincident with such projection.

DIV. 37, PAPER NO. 2
Amendt A

New York, Oct. 17, 1905.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

In the matter of the application of Adolph F. Rietzel for Method of Electric Welding, filed Feb. 24th, 1905, S. N. 247,081;

In reply to the Examiner's communication dated Apr. 12th, 1905, please amend as follows:

Erase beginning line 1, page 1, of the specification to the end of line 7, page 2, and substitute:

My invention relates to the union of plates or sheets of metal, especially in the thinner gages, face to face, and its object is more particularly to provide an efficient and cheap substitute for the methods heretofore employed for uniting pieces of sheet metal face to face. Heretofore in sheet metal working the usual way of fastening two pieces of sheet metal together face to face has been by the employment of fastening screws or bolts or by the use of tongues or projections on one sheet entering perforations or openings in the other sheet or plate and turned down or bent to lock the pieces together. Sometimes such plates or sheets of metal have been united by riveting them together at points sufficient in number or sufficiently near to one another to form a strong and effective means of clamping or fastening the two pieces together.

My present invention provides for the union of plates or sheets of metal together face to face by electric welding, which as ordinarily practised, could not be used for the purpose should it be attempted to unite the sheets together over their whole plane surfaces on account of the large area of surface contact which would exist if the plates were simply laid one upon the

other distinct modification of the form of the plane surface or without some means for restricting the extent of the welded union.

The present invention consists essentially in a welded union of two plates or sheets of metal made by electrically welding them together on their plane faces at a number or multiplicity of distinct or isolated points, which points of union are isolated spots, points or surfaces of union after the completion of the weld. The contact spots or points of union may be fixed or determined by either casting, punching or indenting the metal of the plane surface or otherwise forming the same so as to provide thereon a multiplicity of isolated projections, or said contact spots may be provided by disposing a number of small pieces of metal over said surface, which pieces become united with said surface and with the opposite piece or pieces of metal in the welding process."

Erase the claims and substitute:

1- Metal plates fastened together over their plane surfaces by a number of distinct isolated welds or unions.

2- The method of fastening plates of metal of any gage together by their plane surfaces, consisting in providing a multiplicity of contact spots over said surface, passing a heating electric current over said spots simultaneously, and applying pressure to simultaneously form a multiplicity of mechanically distinct electrically welded points of union on the plane surfaces presented to one another.

3- The herein described method of fastening two pieces of metal together, consisting in providing each plate with a number of projecting contact spots on its plane surface, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other through such spots, simultaneously

applying pressure and completing the process with the formation of a multiplicity of distinct points of welded union coincident with the spots of contact.

4- The method of fastening two plates of metal together consisting in providing between them a number of contact spots for passage of the electric current from one to the other by their plane surfaces, passing a heating electric current through such spots simultaneously, applying pressure and finishing the process with the formation of a multiplicity of points of union over the surfaces presented to one another, as and for the purpose described.

5- The herein described method of fastening two plates, consisting in indenting each plate to form a number of projecting contact spots on a plane surface of each plate, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other and applying pressure to form a multiplicity of points of welded union between the plates at said spot or spots.

Remarks.

There is a radical distinction between applicant's invention and that described in the Hunter combination, in which the purpose is primarily to form in the first place a union of sheets of metal end to end. Applicant's process in substance involves the union of two plates or sheets of metal face to face so as to fasten them together over practically their whole abutting faces. Further, however, the Hunter process involves not the union at a number of distinct points of weld, but as specifically set out, contemplates the melting of the metal so as to make a full transverse weld or as set out at line 68, "a simultaneous series of gradually-extending welds, which ultimately unite" This is a process, which of necessity, involves the formation of the contact spots originally in sufficiently close proximity to allow the welding to extend and merge the spots into one whole

or full weld with necessarily a corresponding expenditure of power incident to the employment of spots in much greater number than is essential to applicant's process. Applicant's invention provides an efficient and cheap substitute for those methods of fastening plates of metal together which have heretofore been employed and which comprise essentially a number of points of mechanical attachment of one to the other by tongues, rivets or similar devices. The Hunter invention might at first blush seem to be of the same nature as applicant's, but when closely examined will be found to be similar only in the point that electric welding is used and that the welding is started over points of contact. This was not broadly new with Hunter as is shown to be the fact by the Robb patent. Applicant's invention is clearly differentiated from both Hunter and Robb in that the union is not formed over the whole cross sectional area of the pieces of metal or portions of pieces to which the welding pressure is applied.

The application has now fully been revised to limit it to the essential differences and it is hoped that a speedy allowance of the application may be had.

Respectfully submitted,

A. F. Rietzel

Adolph F. Rietzel,

Care Townsend & Decker,

New York City.

Please find below a communication from the EXAMINER in charge of the application of your

for Method of Electric Welding, filed Feb. 24, 1905, Ser. No. 247,081

F. I. Allen
Commissioner of Patents.

This is in response to amendment of Oct. 18, 1905.

In the amendment filed Oct. 18, 1905, page 2, line 1, some word has evidently been omitted. It is suggested that without should be inserted after other.

Claim 1 is rejected on Thomson, 396,015, Jan. 8, 1889 (Metal Heating and working, Riveting).

Claims 2, 3, 4 and 5 are rejected on Hunter, 690,958, as they involve the same method. The same steps in the process of welding the plates together are taken in both cases, only that in Hunter the welding heat and pressure are continued until the separate welds unite, while applicant stops short of this, which, however, does not involve invention.

Rule.

DIV. 37 PAPER NO. 4
Sub. Spec.

New York, Oct. 22nd, 1906.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

In the matter of the application of Adolph P. Rietzel for Method of Electric Welding, filed Feb. 24th, 1905, S. N. 247,081;

In reply to Office letter of Oct. 24th, 1905, please amend as follows:

In the title of the invention erase "Method of Electric Welding" and substitute "Uniting the Component Parts of Composite Sheet Metal Structures".

Sub. Spec

Erase the specification and claims and all amendments thereto and substitute:

"The present invention relates to the manner of forming a union of two plates or sheets of metal especially in the thinner guages in those cases where it is desired to form a composite metal structure in which the sheets or plates are securely fastened together at their plane faces.

Sub. D

Sub. Spec.

Heretofore in forming a union between two pieces of sheet metal when it is desired to secure them together at their plane faces, the practice has been to use fastening screws or bolts or tongues or projections on one sheet or piece lapped or turned down upon the other to lock them together.

It has also been proposed to unite the two pieces in order to form the desired structure, by riveting them together at a number of points sufficient in number or suffi-

ciently near together to clamp or secure them firmly together.

The present invention consists essentially of a welded union of two plates or sheets of metal at their plane faces by a multiplicity of distinct or isolated points of electrically welded union.

The invention is especially useful in the manufacture of articles from sheet metal in which the completed article is a composite sheet metal structure.

In carrying out the invention, the distinct or isolated points of welded union are determined by the location or disposition of initial electrical contacts cast, punched or indented in the plane surfaces of the metal or otherwise formed so as to provide a multiplicity of isolated contact spots for the passage of an electric current, which heats the metal at the contact spots or points contiguous thereto to a welding temperature so that on application of pressure the corresponding number of welded points of union are established which unite the sheets firmly together.

Also in carrying out the invention, the initial contact spots coinciding with the finished points of union may be provided by disposing a number of small pieces of metal over the surfaces presented to one another, which pieces become united with said surfaces in the welding process.

In carrying out the invention, the points of contact are separated from one another or so disposed that the unions will not run into one another. By so spreading the spots, it is possible to effect the union with less consumption of power than would be required if they were so close together as to run into one another, since in the latter case,

it is obvious that a large number of spots would be required and consequently a larger amount of heating current would have to pass in order to heat them all to welding temperature. It will be found, however, that a perfectly firm and tenacious union of the plates can be secured when the distance between the spots is made such that the union is at a number of isolated of distinct spots of welded union instead of by a continuous line.

Figures 1, 2, 3, 4 and 5 show pieces of metal of different forms interposed between the electrodes of an electric welding machine; Figs. 6, 7, 8 and 9 show modifications in the form and disposition of the isolated projections.

ub. Spec. er C. Fig. 10 shows 3 plates assembled for welding together.

Referring to Figs. 1, 2, 3, 4 and 5, the electrodes of an electric welding machine are indicated at A, A'. These electrodes, as usual in the art, supply heating current to the work interposed between them, and also preferably serve as the means through which welding pressure may be applied to the work while heated to welding temperature. In Fig. 1, piece B' is a plate or sheet of metal to be welded at its plane surface to an opposite plate or sheet B. In this figure the plate B' has a number of isolated contact spots c, which may be formed by indenting the plate and which projections engage directly with the opposite plate B.

As before stated, these spots are isolated from one another and separated by such spaces that after the application of the heating current and the pressure the union will be at a number of distinct or isolated welded points and will not consist of a continuous line of unions coincident with said spots as would be the case if the spots were close together and larger in number so as to require more power and to cause

the welds to run into one another.

In Fig. 2 both plates have projections which engage with one another, although, and as indicated in Fig. 10, each of the contact spots or projections c upon one plate might engage with the plane surface of the opposite plate.

In the operation of forming the weld, current is passed from one plate or piece to the other through the con-
Sub. Spec. act spots or projections c, raising themetal to welding temperature at such points, and the application of welding pressure in the usual manner forms spots of welded union coincident with such points or projections andwhich firmly unite the pieces together. The contact points, spots or projections might be formed on either or both surfaces by casting the projections thereon which modification is indicated in Figs. 3 and 4 wherein the pieces B, B' are supposed to be cast metal plates or pieces.

In Figs. 1 and 2 the plates are supposed to be of sheet metal. These plates or projections may be formed, however, in any desired way upon the surface with which the welded union is to be made. Instead of providing contact spots consisting of projections from the plane surfaces themselves, they may be provided by interposing separate pieces of metal, C', as indicated in Fig. 5 which are disposed in any desired number, according to the number of points of union desired, over the plane surface with which the welded union is to be formed. These different spots or projections may take any desired form or be disposed in any desired relation to one another and to the boundaries of the surface with which the welded union is to be made.

As shown in Fig. 6, they may be rounded projections disposed near the edges of the plate or they may be somewhat elongated projections as shown in Figs. 7 and 8 and symmetri-

cally or irregularly arranged as shown; as shown in Fig. 9, they may be a combination of round and elongated projections.

As will be obvious their form and disposition may be greatly varied, and as already stated, the manner of producing them is capable of indefinite variation.

Fig. 10 illustrates the welding of 3 plates or sheets together. The number can be extended indefinitely, and while ordinarily only two pieces would be welded at a time, more may be welded provided the current is sufficient.

The invention is of special utility in the manufacture of articles from sheet metal which are stamped out to different forms, and which heretofore have been joined in a mechanical way requiring expensive dies and tools to produce the finished article. When the invention is employed in this field of manufacture, all that is necessary in order to provide for the union of the pieces is to form or provide the spots or projections in any desired way or in any convenient form on the surface to be united, either by punching, indenting or otherwise forming them up or by providing isolated metal pieces to be united in an electric welding machine and weld them together as already described.

Sub. Spec.

I am aware that it has been before proposed to unite two plates or sheets of metal electrically by providing points of contact so disposed that on the passage of the current, the softened metal of contiguous spots will run together making a continuous welded line, but in my plan of union no such action takes places, since the number of spots or their proximity to one another is determined by the number of distinct spots of welded union required to give the desired strength and is not such as to cause the molten metal to flow and form a continuous line of molten metal uniting all the spots.

What I claim as my invention is:

1- Metal plates fastened together at their plane surfaces by a number of distinct or isolated welds formed between such surfaces.

2- Composite sheet metal work formed by a union of the component sheets at a multiplicity of distinct or isolated points of electrically welded union over their abutting faces.

3- Articles of composite sheet metal manufacture having their component parts united at their plane faces by a multiplicity of distinct or separate points of electrically welded union.

4- The herein described method of fastening two plates or sheets of metal of any guage together at distinct points of union disposed over their plane surfaces, consisting in providing a multiplicity of electrical contact spots over said surfaces coincident with the separated spots of union, passing electric current from one plate to the other through said contact spots simultaneously and applying pressure to effect the union at the distinct or isolated spots between said plane surfaces.

5- The herein described method of fastening two pieces of metal together by providing each plate with a number of projecting contact spots on its plane surface disposed at such distances apart that the unions will not run into one another but will, nevertheless, firmly hold the plates together, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other through the spots and simultaneously applying pressure thus uniting the plates at a number of distinct points of welded union.

6- The method of fastening two plates of metal together

1742

at a multiplicity of distinct or separate points of welded union, consisting in providing between them a number of isolated contact spots adapted to pass an electric current from one to the other but so separated that the electric welds will not extend into one another from one spot to the next, passing a heating electric current through such spots simultaneously and applying pressure as and for the purpose described.,

. Spec.

7- The herein described method of fastening two plates together at a multiplicity of distinct mechanically separated points of welded union, consisting in indenting each plate to form a number of projecting contact spots on the plane surfaces which are to abut, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other thereby forming a number of distinct zones or points of heated metal heated to welding temperature, and applying pressure to complete the union of plates by a number of mechanically distinct unions."

REMARKS.

We present herewith an entire new specification and claims which more fully set forth the invention and distinguish the same from anything disclosed in the Thomson or Hunter patents. The Hunter invention both in conception and execution is radically different from applicant's invention. In Hunter the primary purpose was to form a ~~x~~ continuous line of welded union. In applicant's case the desgin was, broadly speaking, to form a union at a number of distinct or isolated spots chosen as to frequency or number or distance apart for the desired strength of union face to face of two plates of sheet metal. In Hunter the requirements of his process are not satisfied unless the initial contact spots are so close together that the welds will extend into one another to make

a continuous line of union. It is distinctly stated in his specification that when the projections melt, small lakes of molten metal are formed which quickly spread and unite. As a matter of fact this requires that the points or spots should be very close indeed to one another and so that it would not be possible, as suggested by the examiner, to stop the process at a point such that separate welds would be formed. This would be quickly appreciated by the examiner if he should see the process of welding as carried out by applicant in the uniting of two plates or sheets of metal face to face. As well understood by those skilled in this art, the initial pressure during which the heating to welding temperature takes place is accompanied by a pressure upon the work sufficient to insure good connection electrically, but this pressure is not the efficient welding pressure. As soon as the welding temperature has been attained the weld is effected by a smart or quick application of the heavy or welding pressure. The suggestion of the examiner practically amounts to the suggestion that this heavy welding pressure could be stopped at an intermediate stage in practising the Hunter invention so as to produce separate welds. To this the applicant replied that it would be, in the first place, impossible for the operator to adjust or stop this welding pressure at any particular stage of the operation of effecting the union no matter what the number of proximity of the spots and that in the next place it is essential in the Hunter process that the projections should be so near together that the small lakes of molten metal or fused metal will be formed and will quickly spread and unite so x that obviously distinct points of union are impossible from the very nature of the process as detailed by Hunter.

It must be further apparent that in the Hunter process it is essential that a very great number of points of

union must be used or any given area of plates to be united, as compared with the number required in applicant's process, and hence when economically considered the consumption of power must be much greater in Hunter's case then in applicant's.

Moreover, as a structure a piece of composite sheet metal work in which the union face to face is effected by a multiplicity of distinct points of welded union between the abutting plane faces is a distinctly different thing from a structure like Hunter's in which xx two plates of metal are united simply by lapping their ends for a shorter distance upon one another and forming a continuous line of welded union extending transversely across the plates. From every standpoint, the two inventions are distinctly different.

Regarding the Thomson patent, we have simply to say that this describes the riveting of pieces of metal together by a number of rivets. This is quite a different thing from the union of two plates of sheet metal face to face by isolated electrically welded spots on the abutting faces of the plates.

A reconsideration is respectfully requested.

Respectfully submitted,

Please find below a communication from the EXAMINER in charge of your application of

#247,081, filed February 24, 1905, for Uniting the Component Parts of Composite Sheet Metal Structures.

F. I. Allen

Commissioner of Patents.

This action is in response to applicant's communication of October 23, 1906.

In line 16, page 3, insert A, before "A'".

The claims present nothing patentable over Hunter of record. It is held that there is no invention in merely spacing the projections "b" further apart than Hunter does, especially if it is not deemed necessary to have a continuous weld. As it is old to unite plates at a multiplicity of distinct or isolated points by rivets, as shown in Thomson of record, it is held that to decrease the number of projections on Hunter's plates so that there will be a multiplicity of distinct or isolated points of welded union does notamount to a patentable distinction. With regard to having projections on both plates, attention is called to lines 52-54, page 3 of the Hunter patent, in which he states that "the projections or points of contact" are "upon the edges of one or both plates".

Claims 1, 2, and 3 are also rejected on Thomson. In lines 25-33, page 1, he states that, by allowing the current to pass for a longer period, he can weld the pieces together around the rivet by the application of pressure. From this it follows

1746

that the plates will be united at a multiplicity of distinct and isolated welds. It is true that the plates are riveted at these points but they are also welded together.

The claims are rejected.

DIV. 16, FILED.

PAPER NO. 6
AMENDMENT. B

New York, Nov. 16, 1906.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

In the matter of the application of Adolph F. Rietzel for Uniting the Component Parts of Composite Sheet Metal Structures, filed Feb. 24th, 1905, S. N. 247,081;

In reply to Office letter dated Nov. 9th, 1906, please amend as follows:

Erase the paragraph at the top of page 2 of the substitute specification filed Oct. 23rd, 1906 and beginning with the words "The present invention consists essentially" and substitute the following:

"The present invention consists essentially of a welded union of two plates or sheets of metal at their plane faces formed wholly by a multiplicity of distinct or isolated points of electrically welded union coincident with and composed of the material embraced in raised eleptrical contact spots in the plane surfaces of the metal."

In the paragraph beginning with the words "In carrying out the invention" on the same page and in the third line thereof insert a "," after the word "of", and before the word "initial" insert "and embrace the material comprising"

Erase the claims 1, 2 and 3 and substitute:

"1- Metal plates fastened together at their plane surfaces by a number of distinct or isolated welds between such

surfaces formed wholly of portions of the plane surfaces of said plates.

2- Composite sheet metal work formed by a union of the component sheets by a multiplicity of distinct or isolated welds disposed over their abutting faces and each coincident with and comprising material embraced in raised electrical contact spots in the plane surfaces of the metal, as and for the purpose described.

3- Articles of composite sheet metal manufacture, wholly united at their plane faces by a multiplicity of distinct or separated points of electrically welded union composed of the material of the plates themselves."

R--E--M--A--R--K--S.

In the foregoing amendment of claims 1, 2 and 3, we have differentiated applicant's invention from anything contained in the Thomson patent. That patent constitutes the prior art recognized by applicant in his specification and a careful consideration thereof will make it clear that applicant has made a distinct advance in this art worthy of a patent. It is clear that in the Thomson patent the use of a rivet is made essential. It does not matter whether the heating is carried on to the point such that the rivet itself will, at its edges, become fused to the edges of the opening in the metal plates or that he describes a continuation of theheating until the contiguous portions of the plate may become welded together. The rivet is there and must be provided to become an essential part of the union. To produce the union, according to the Thomson patent, there is involved a preliminary punching of the plates with holes, the provision of a rivet, the insertion of the rivet in the hole and the application of a peculiar form of

die to each of the rivets separately, the form being adapted to the particular shape of rivet head which it is desired to make.

In applicant's welded union, there is a distinct new thought that a union might be secured by a simple union of the plane faces of the sheets at a number of distinct or isolated points and without the use of any rivets, by simply making the proper initial contact spots on the plane faces of the metal sheets and letting such initial contact spots become embraced in the union so as to constitute practically the uniting material.

There is nothing in the Thomson patent suggesting such a thing for it does not say a work about producing any projections or contact spots in the plane surfaces of the metal sheets and unless that be done, no union, such as mentioned in the examiner's letter, would be possible without the use of the rivet to form the initial heating path for the current. Only upon the theory that it would be possible and also an obvious thing to omit the rivets of Thomson, can the suggestion of welding at points around the rivets, as contained in that patent, be of any avail to anticipate applicant's invention, but as just stated, to omit the rivets in Thomson would not be possible for there would then be left no means for localizing the heating current. These considerations we submit are sufficient to make the Thomson patent insufficient as a reference or anticipation of applicant's invention. We also, however place out objection to the sufficiency of that reference upon the distinct fround that applicant's invention as set out and claimed by him excludes the use of rivets and that there is no suggestion in the Thomson patent of omitting the rivets, nor would it be obvious to any one that such rivets could be omitted and the proper union secured without them.

In regard to the Hunter patent and the suggestion now offered by the examiner that Hunter might place his contact

points at distances further apart than is described in his patent and thereby satisfy the requirements of applicant's invention we respectfully reply that there is no such suggestion in the Hunter patent and that, moreover, if the distances were made substantially greater, it would be either impossible to practise the Hunter invention which requires that small lakes of molten metal shall be formed, that, as the specification states,"quickly spread and unite", or else the pressure and passage of current would have to be continued so long as to result either in the complete melting down of the whole material of the plates and the consumption of an inordinate amount of power. In other words, there is a distinct and unmistakable difference between the Hunter process which requires such propinquity of the contact spots that by the use of current sufficient in amount or in period of application, there will be a merging of the welds into one another to make practically one weld by the flowing of small lakes of molten metal into one another, and a process in which the contact spots are chosen with reference to the formation of distinct points of weld by the application of the usual current and pressure, the number of points being chosen wholly with reference to the production of a union which, in the multiplication of the isolated unions, shall produce a fastening of the plates together with the desired strength.

The suggestion of the Examiner that the latter process is suggested by Thomson taken in connection with Hunter clearly is of no force in view of the fact that the Thomson process as outlined in his patent could not be practised at all if the rivets were dispensed with or, in other words, the rivets are with Thomson the essential means for forming the paths of the initial heating current and in fact would be substitutes to that extent of the contact projections formed by indenting the plates in the manner proposed by applicant.

It is clearly going beyond the point by any possibility hinted at in the Thomson patent to say that that patent discloses to one skilled in the art the idea of dispensing entirely with the rivets, and as a substitute for such rivets in forming the initial contact or path between the jaws of the machine, using contacts formed by indenting the plane surfaces of the metal at points coincident with the axes of the rivet holes

It is alike outside of any possible suggestion contained in the Thomson patent to say that the patent discloses the idea of omitting the rivets altogether, leaving the holes punched in the material and raising the material around the punched holes so as to form welds over the areas around said holes. We submit not only that neither of the two patents discloses the invention for which applicant seeks a patent. Nor can it be justly said that taking the two patents together, they furnish an obvious suggestion to one skilled in this art of applicant's invention. The fact of the matter is that the process and the product devised by applicant are a distinctly new thing in this art and they mark an advance in the art by a step much broader than anything separating the Hunter patent from the art previous to his date of filing, April 7th, 1898.

Respectfully submitted,

Letter

New York, May 27th, 1908.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:-

In the matter of the application of Adolph F. Rietzel, for Uniting the Component Parts of Composite Sheet Metal Structures;

We understand that the Examiner, in view of the representations made at the personal interview referred to in our communication of April 20th 1908, and on further consideration of the case in connection with the specimens filed at that time, is prepared to recede from his position that there is no patentable merit in the case over the Hunter patent but that he holds to the view that the claims do not clearly express the difference over the Hunter process and apparatus in this respect, to wit; that the metal between the points in the present process is not brought to the plastic or welding condition.

Upon this point, to wit; whether the claims bring out this difference we ask a reconsideration.

It would seem clear that this difference is clearly stated in claim 1 by the term "isolated welds" and in claims 2 and 3 by the terms or expressions "multiplicity of distinct or isolated or separated points of union".

The same idea also is, we think, clearly expressed in claim 4 and certainly in claim 5 by the statement that the contact spots are so far separated that the welds or unions will not extend into one another.

The same idea is also expressed in claims 6 and 7.

In view of the facts, as we understand them, we accordingly request a further action on the merits of the case which, in our view, should be an allowance of the case on the claims in the form in which they now stand.

Respectfully submitted,

A. F. Rietzel

for "Method of Electric Welding", filed Feb. 24, 1905, Serial No. 247,081.

E. B. Moore

Commissioner of Patents

In response to communication of May 28, 1908.

This case has recently been transferred to division 26.

The Examiner now in charge of this case has no knowledge of the personal interview referred to in the applicant's letter of above date, and is aware of no reason why the appeal should be withdrawn and the claims reconsidered. The applicant's request for reconsideration is accordingly refused, and the appeal should be prosecuted.

The Examiner proposes to direct the attention of the Board of Examiners-in-Chief to the British patent to Harmatta, 22,981 of 1903, Class 219, Welding (see Fig. 4 and lines 32 and 33, page 5), as additional ground for the rejection of claims 1, 3, 4 and 6. Fig. 4 of this patent shows a spot weld, which takes the place of a rivet, and it is not considered to be a patentable improvement to join two sheet metal plates by a number of such "spot welds".

U.S.PATENT OFFICE DIVISION 26

New York, Nov. 24th, 1908.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

In the matter of the application for patent of Adolph F. Rietzel for Composite Metal Structure, filed February 24, 1905, S. N. 247,081:

We hereby amend as follows:

Erase the specification and claims and all amendments thereto and substitute the following:

My invention relates to the manner of uniting or fastening two pieces of metal to one another and its object is more particularly to afford a substitute for the manner of uniting pieces of metal as heretofore practised in the art of electric welding.

As applied to sheet metal manufactures the object is to afford a cheap and practical substitute for riveting and other methods of mechanically securing the two pieces of metal together.

As applied to this branch of the metal working arts, the invention affords a means whereby articles of composite sheet metal manufacture may be made up by fastening the pieces of metal constituting the structure with a perfectly secure union by a process that can be economically conducted.

Briefly stated, the invention consists in electrically welding pieces together in a spot or spots definitely located in and involving a portion only of

their meeting surfaces as hereinafter more particularly described and claimed.

It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over ~~the~~ substantially the whole area of the opposed portions of said pieces. It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces.

A weld formed according to my invention is distinguished however from such prior welds by the fact that a portion only of the opposed surfaces is welded together, such portions being coincident with an limited to spots in the areas of such opposed surfaces in which spots the heating electric current is localized or confined in any desired way so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together.

My invention is particularly valuable in fastening of pieces of sheet metal together because not only does it limit the amount of electric energy required very considerably as compared with the prior methods of union, but it also diminishes the liability to burning of the metal which is liable to occur when the attempt is made to form a union of two sheets of metal by an

electric welding process over substantially the whole area of the meeting or opposed surfaces.

In carrying out my invention any desired number of spots of union may be employed, such number depending obviously upon the extent of the meeting surfaces which are to be fastened together and also upon the strength of the union desired.

In carrying out my invention the localization of the flow of heating electric current and of welding pressure to the desired spot or spots may be brought about in any desired way. One of the preferred ways is by providing between the meeting surfaces or portions of the pieces to be united suitable conducting projections or points at the spots of union, which projections or points carrying the heating electric current from one piece to the other are so located in the meeting surfaces and are so separated from one another that on the application of the welding pressure the welded union resulting will be localized in the, area of the opposed surfaces and will be substantially coextensive in area with the restricted area of the path of the effective heating current. Various ways of providing such points or projections will occur to those skilled in the art.

The preferred method is to indent the metal from the side reverse to that on which the union is effected by a suitable tool, the projections thus formed affording points for the passage of the electric current. This method is preferable also because it permits the wedling to be produced at a multiplicity of spots simultaneously through the application of pressure over the whole rear surface of the plate, the points or pro-

jections in that case serving not only to localize the flow of the heating current but also to localize the welding pressure. In the preferred manner of carrying out my invention in the case of sheet metal manufacture I provide projections from the meeting surfaces of both pieces that are to be united. Said projections may also be provided by interposing between the two plane sheets small pieces of conducting material which act in the same manner when the sheets are brought together, as projections which localize the heating current and the pressure. It will be understood, however, that in the latter instance as in the former, these pieces are so small and are placed such a distance apart that on the application of welding pressure there will be no running of the welds into one another but that the final union will be in spots only leaving well-defined areas on the meeting surfaces, in which the surfaces either lie in contact or separated from one another by a very think space.

From the foregoing it will be seen that my invention is distinguished from prior methods of welding pieces of metal together in that it may be very cheaply practised, because no attempt is made to weld over the whole of the opposed surfaces of the welded pieces; but on the contrary the union is at a spot or spots only which in ordinary cases will afford as strong a union as would be produced by the riveting of the pieces.

The invention further has the advantage that not nearly so much electric energy is required as is necessary when the electrically welded union extends over the whole area of the opposed surfaces. Moreover, the danger of burning when the attempt is made to weld two sheets

of metal together by a lap weld is largely eliminated.

In the accompanying drawings Figs. 1, 2, 3, 4 and 5 illustrate some of the ways in which the pieces of metal to be united may be prepared for the welding according to my invention.

Figs. 6, 7, 8, and 9 show modifications in the form and disposition of the contact projections which result in the spots of electrically welded union.

Fig. 10 shows the assembling of three plates together for welding according to my invention.

In the various figures of the drawing the invention is illustrated as carried out with two sheets of metal B.B'. In Fig. 1, plate B.' only is provided with the distinct or isolated spots (c) or projections for the flow of the electric current, to the plate B. which spots or points may be formed by indenting the plate with a suitable tool. The spots are located so far from one another that on the application of pressure coincidentally with the flow of electric current from one plate to the other there will be a number of distinct areas or spots of electrically welded union of the plates separated by well-defined areas on the meeting surfaces in which no union takes place. The resultant is however a fastening of the plates together securely and which is practically as effective as if the attempt were made to form a welded union over the entire areas of the meeting surfaces. Obviously, the greater the distance between the spots the lesser the number that would be used and hence the lesser the consumption of energy in effecting the weld. This is of considerable importance where the meeting areas are large or

where a considerable amount of work has to be done. The welding pressure is conveniently applied by conducting-blocks or electrodes, A, A', between which the two pieces B, B', are assembled. These electrodes, A, A', furnish the heating current while applying the pressure, the localization of the pressure in the spots being brought about in this instance by the pointing of the surfaces at point c.

In Fig. 2 both plates are provided with projections the points of which engage with one another, the pointing being produced by indenting the metal sheets from the rear.

Fig. 3 illustrates the localization of the welding by casting projections upon one of the sheets and Fig. 4 by casting projections on both pieces. The localization of the welding in spots might be affected as illustrated in Fig. 5 by interposing small pieces of metal at the spot or spots of desired union, these pieces operating when the plates are brought together in the same way as the projections before referred to. The number and size of the pieces and their distance apart is in this case, as before, so chosen that the application of pressure together with the flow of heating current from one plate to the other will result in a union of the two pieces over their opposed surfaces in spots only thereon.

Fig. 6 shows how the spots might be disposed to fasten the pieces together in distinct spots around their edges.

As shown in Figs. 7 and 8 the projections, instead of being round, might be somewhat elongated and

irregularly or symmetrically arranged.

Fig. 9 shows round and somewhat elongated projections combined.

In all these instances however, the union over the surfaces of the plates is confined to spots or areas which are of comparatively small extent as compared with the total area of the meeting surfaces. As will be obvious, the form and disposition of the points or projections of initial contact for flow of the electric current and localization of the pressure may be greatly varied without departing from my invention.

Fig. 10 illustrates the welding of three plates of sheets together when superposed.

My invention is especially useful in the manufacture of articles from sheet metal which are stamped out to different forms, and which have heretofore had their component portions united by riveting or other purely mechanical expedient which is not only expensive but requires generally special tools and results in many cases in an insecure union. When the invention is employed in its perferred form or manner of practice in the field of sheet metal manufacture all that is necessary is to provide the contact spots or projections as already described and then to assemble the pieces in an electric welding machine and weld them together as already set forth.

Insert E2

Sub. F'

What I claim as my Invention is:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at a spot or spots only of their juxtaposed or opposite faces.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other, while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current, and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces, so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other, while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the

pieces are not welded together.

5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded separated from one another by areas of no union.

6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

7. The method of welding two pieces of metal together, consisting in superposing said pieces with their surfaces at which the union is to take place, superposed or presented to one another, pressing the pieces together, and passing a heating electric current from one to the other while, and localizing the heating current simultaneously in a number of distinct or separate spots of limited area, separated from one another sufficiently to secure a union of the pieces in a number of corresponding distinct spots surrounded by and separated from one another by comparatively distinct areas in which no union exists.

8. The method of uniting two pieces of metal, consisting in providing between their meeting surfaces a

number of projections, spaced apart as described, pressing the pieces together and passing an electric current through said projections while confining the welding area of such current to said projections and the areas immediately surrounding the same so as to leave distinct areas around between spots in which no welding shall be produced.

9. The method of fastening two plates of metal together at a multiplicity of distinct or separate points of welded union, consisting in providing between them a number of isolated contact spots adapted to pass an electric current from one to the other but so separated that the electric welds E4 will not extend into one another from one spot to the next E4, passing a heating electric current through such spots simultaneously and applying pressure as and for the purpose described.

10. The herein described method of electrically welding two plates or sheets of metal of any guage together by distinct spots of union disposed over their plane surfaces, consisting in providing a multiplicity of electrical contact spots coincident with the separated spots of union and disposed at such distances apart that there will be well-defined areas between spots through which the electric current will not flow, passing electric current from one plate to the other through said contact spots simultaneously and applying pressure as and for the purpose described.

11. The method of fastening two sheets of metal together, consisting in providing between them a number of isolated contact spots for the passage of the electric welding current, said spots being adatped to ini-

tially hold the plates apart and being separated from one another a sufficient distance to confine the welding to distinct areas or isolated spots, passing a heating electric current through a number of said contact spots simultaneously and pressing the plates together as and for the purpose described.

12. The method of fastening two plates of metal together, consisting in furnishing a surface of said plates with a number of projecting contact spots for the passage of welding electric current and disposed at such distances apart that on the application of pressure the welds will not run into one another, superposing said plates, passing a heating electric current from one to the other over said separated spots and applying the pressure to produce a spot-welding of the plates to one another as and for the purpose described.

13. The herein described method of fastening two pieces of metal together by providing each plate with a number of projecting contact spots on its plane surface disposed at such distances apart that the unions will not run into one another but will, nevertheless, firmly hold the plates together, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other through the spots and simultaneously applying pressure thus uniting the plates at a number of distinct points of welded union.

14. The method of uniting two sheets of metal face to face, consisting in indenting the material, super-

posing the plates with the points of the indentations engaged, passing an electric current from one plate to the other through said point-or points simultaneously, and applying pressure while confining the area of heating to welding temperature to a circumscribed area or spot to unite the pieces in a distinct spot or spots of small extent in the whole area of the opposed faces.

15. The herein described method of fastening two plates together at a multiplicity of distinct mechanically separated points of welded union, consisting in indenting each plate to form a number of projecting contact spots on the plane surfaces which are to abut, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other thereby forming a number of distinct zones or points of heated metal, heated to welding temperature, and applying pressure to complete the union of plates by a number of mechanically distinct unions.

16. Composite metal work, having its component pieces welded together at one or more spots localized on their meeting surfaces or portions so as to be separated from one another on said meeting portions by distinct areas which are unwelded.

17. Metal plates fastened together at their meeting portions by a number of distinct or isolated welds formed at spots of such restricted area and so separated from one another that when welding electric current is passed from one to the other at said spots, the metal between the spots will not be brought to plastic or welding condition.

18. Metal plates arranged face to face and fastened together on their plane surfaces by a number of distinct or isolated electric welds formed of the metal of said plates in spots separated from one another to such a distance that in passing the heating electric current from one plate to the other there shall be distinct areas in which no effective welding current can pass.

Sub. E7

19. Composite sheet metal work formed by a union of the component sheets at a multiplicity of distinct or isolated welds, comprising raised electric contact spots in the plane surfaces of the metal of said plates, said spots separated from one another a sufficient distance to localize the welding in distinct spots separated by areas in which there is no union.

D Erased Pr F

20. Articles of composite sheet metal manufacture, united at their plane surfaces at a number of spots of electrically welded union involving the material of said plates and separated from one another to such a distance that in passing current from one plate to the other simultaneously at the points where said spots are located, there will be distinct areas between spots practically unaffected by the current.

Insert-E8 E 8

21. Composite metal work consisting of superposed pieces secured together by a welding of the same on their opposed faces by distinct spots of welded union, isolated or separated from one another by unwelded portions of such faces.

Sub. E9

22. Composite sheet metal work having its component parts welded to one another on their opposed faces at a multiplicity of distinct or separate spots of electrically welded union, substantially coextensive in area with the restricted area of the path of the

Sub. E10 E10 Erased Per F

effective heating current so as to produce a welding in spots.

23. Metal pieces welded together in a spot or spots definitely located in and involving a portion only of their meeting surfaces as and for the purpose described.

REMARKS:

We submit herewith substitute specification and claims in the above-entitled case, together with an affidavit of the inventor, making oath to facts showing a completion of the invention in this country before the legal date of the foreign patent to Harmatta, cited by the Examiner as an anticipating patent.

We also submit an expert affidavit of Elihu Thomson, the inventor of the electric welding process, distinguishing the invention claimed by applicant from the invention as disclosed in the Hunter patent and in his own patent for electric riveting which has been cited by the Examiner.

The specification and claims now submitted have been drawn with a purpose of more fully and exactly bringing out the essential difference between the Rietzel invention and the Hunter invention or the invention in the Robb patent, and along the lines which led the Examiner having charge of this case when it was appealed, to consent to the remanding of it to him for further consideration, after a personal interview in

which the actual differences between the Rietzel and Hunter inventions were pointed out to and admitted by the Examiner. The gist of his objection to the allowance of the case at that time was that those differences were not sufficiently brought out in the claims appealed.

We think there can be no question as to the sufficiency of the specification and claims now submitted to distinguish the invention from the patents cited.

Applicant has made a valuable contribution to the art and one that has gone into very extensive use in the manufacture of sheet metal utensils. The invention marks a distinct step forward in the art and we are confident that the existence of an essentially novel invention clearly distinguishable from anything shown in the patents cited will be admitted by the Examiner. We may add that as to the Robb patent it is apparent that the patentee contemplated only the formation of a weld which would not be limited to a spot in the opposed or meeting surfaces but would spread and practically involve the whole of said opposed surfaces and would be coextensive in area with the cross-sectional area of one or both pieces taken on a line immediately back of the welded union or transverse to the line of welding pressure. It is true that Robb by a special expedient starts the heating at a point of comparatively small extent just as it had been started previously in the art by pointing the pieces. The ultimate union, however, was not limited in area or extent in the manner proposed by applicant, but was in fact a welded union of exactly the same kind as had been previously secured in the art by pointing the pieces.

Respectfully submitted,

(15) A. F. Rietzel By Townsend & Decker Atty's

Hon. Commissioner of Patents,

Washington, D. C.

Sir:-

In the matter of the application of ADOLPH R. RIETZEL, filed Feb. 24th, 1905, S. N. 247,081 for Uniting Sheet Metal By Electric Welding.

AFFIDAVIT.

County of New York)
State of New York) ss

ADOLPH F. RIETZEL being duly sworn deposes and says that he is the applicant who filed the above entitled application for patent; that some time in June 1904 he successfully practised the invention in said application by uniting two halves of a sheet metal pulley in a electric electric welding machine at the shop of the Thomson Electric Welding Co., in Lynn, Mass.; that the piece of sheet metal herewith attached and marked:"specimen of pulley C. F. Tiedhenr Jr. .....N.P." is a duplicate of one of the halves of the pulley to which he at that time applied the invention; that the contact points or projections formed in the sheet metal were in the first instance made by filing the metal to leave the contact points or projections, indenting not being available at that time, but that in subsequent operations in which his invention was employed the projections were made by indenting the sheet metal, and that the invention was frequently practised by him successfully at the shop of said Company on a standard welding machine; that in conducting the operations on such machine he employed a pair of contacts fitted in the jaws of the

machine and formed at their outer ends so as to fit into the cup shaped portion of the halves of the sheet metal pulley to be welded, thereby supporting the two halves with the contact projections engaged with one another; the two halves being in contact by the projections while assembled in the machine, electric current was caused to pass through the two halves by the contact projections, and pressure was then applied in the usual way practised in electric welding by the standard machine in which the operation in question was conducted; the operations above recited as conducted by him were uniformly successful and demonstrated clearly that the invention was complete in all particulars, and that the said invention has been since practised on innumberable occasions in substantially the same way for uniting pieces of sheet metal such as the halves of sheet metal pulleys of the form shown in the exhibit and of other forms and of other sizes, many of much larger size than that of the exhibit; that he does not know and does not believe that the invention aforesaid has been in public use or on sale in this country, patented or described in a printed publication in this or any foreign country for more than two years prior to his application and that he has never abandoned the invention.

Adolph F. Rietzel

Subscribed and sworn to by the aforesaid Adolph F. Rietzel before me this 23d day of October 1908.

APPLICATION ROOM
DEC 9 1908
U.S.PATENT OFFICE

IN THE UNITED STATES PATENT OFFICE.

In the matter of the application of
Adolph F. Rietzel, for Electric Welding,
filed Feb. 24, 1905, S. N. 247,081;

AFFIDAVIT.

County of Essex / New-York, } ss--
State of Mass. / New-York, }

Elihu Thomson, being duly sworn, deposes and says that he is and has been for many years past the consulting engineer of the Thomson Electric Welding Co.;

That he is the originator and patentee of the process for electric welding now, and for many years last past, in extensive and commercial use, which process was patented to him by United States Letters Patent dated Aug. 10, 1886, Nos. 347,140, 347,141;

That he is familiar with said process in all of its aspects, details and applications and has practised it himself on innumerable occasions and is the inventor and patentee of numerous modifications and applications ofthe process and of machinery and apparatus for carrying the same into effect;

That he is familiar with the process of electric welding set forth in the above entitled application of A. F. Rietzel for uniting sheets of metal together by what has been known as the "spot welding process" and which forms a practical substitute for the riveting of plates together or for other mechanical expedient for fastening them together face to face;

That one of the methods of uniting pieces of metal together by riveting and for which the aforesaid spot welding process forms a valuable substitute was patented by him by United States Letters Patent dated Jan. 8, 1889, Patent No. 396,015;

That he has read and is familiar with the patent of R. M. Hunter, No. 690,958 for method of electric welding; that said process of welding as set out in said patent is distinctly different from the "spot welding process" aforesaid, in that the purpose of the inventor and patentee, Hunter, was clearly to make a lap joint between two pieces of metal by uniting them over substantially the whole area of the lapping surfaces; that there is nothing in said patent, by implication or otherwise, hinting at the uniting of the lapped surfaces by spots only of welding but that the whole purpose of the patentee, as disclosed by the specification of the patent was to produce a joint in which the welding area is substantially coextensive with the area of the overlapping or opposed meeting surfaces;

That in addition to the explicit statements in the specification the Fig. 4 of the drawing evidences the clear intention of the patentee to make a joint which would not be a spot welding joint but a joint practically coextensive in area of actual union with the area of the overlap, for in said figure it may be seen that the dotted circles showing the merging of the welds or areas of fusion in a line transverse to the strips of metal also are of a diameter practically measured by the extent of the overlap;

That if the metal be heated as the patentee proposes so as to form small lakes of molten metal which will quickly spread and to unite, then the areas of union which

the patentee presupposes in his Fig. 4 to be distinct circular areas would spread irregularly and there would not even be any triangular small areas near the edge of the overlap such as he has supposed would exist; that the production of a heated joint by the formation of liquid pools between the projections, as proposed in the patent, is impractical for the reason that the metal could not be heated to the degree of liquidity without danger of melting the whole sheet itself and that on the other hand if the projections be placed so near together as to permit the welds to unite by the spread of the merely plastic portions so as to merge into one another, the process would be in no substantial way distinguishable from any case of plane lap welding by the electrical process as practised for many years previously to the granting of said patent;

That in the invention of Mr. Rietzel aforesaid, the object and essential operation are entirely different from that of the Hunter process or invention, for the reason that there is no purpose in the Rietzel invention of forming a lap weld continuous over thewhole opposed surfaces of the sheet metal pieces but on the contrary the purpose is distinctly to limit the welding to a mere spot or spots, forming, in effect, a substitute union for that made heretofore, by perforating the plates at the spot or spots of union and then inserting a rivet and heading down said rivet;

That in the Rietzel invention, in other words, themechanical union of the plates is not over the whole area of the opposed or meeting surfaces but at a number of isolated places which are, strictly speaking,

spots, inasmuch as the welding portions of the plate form ~~its~~ portions only of their meeting surfaces and are separated from one another over large areas by disunited portions, said disunited areas being anything desired, consistent with the desired strength of the ~~x~~ composite piece. It is therefore possible and practicable to get the desired strength of union with the expenditure of much less labor and electric energy than would be the case either by the riveting process or by the attempt to start the welding at a number of points sufficiently near together to cause merging of them into a continuous or unbroken area of welded union such as lies at the foundation of the Hunter process.

In other words, in the Rietzel invention there is no such thing as the flowing of the zones of heated metal together and no such thing as a lap joint, the area of union in which is coextensive with area of the overlap as shown and described in the Hunter patent.

The spot welding as contemplated by the Rietzel invention is entirely different in conception and application and affords a welding substitute for a riveted union. There is no welding over the areas between the spots at which the heating current starts and in fact there may be such want of contact and union over such areas, as to allow a liquid to leak through between the plates whereas in the Hunter process the object, as set out in his specification, is to form a joint that shall be liquid-tight.

The accompanying specimen of work marked "Rietzel Exhibit #1 John A. McMannus, Jr. N. P." and which I further identify by marking my initials "E.T." upon

the card attached is a sample of work made according to the Rietzel invention.

The accompanying exhibit marked "Rietzel Exhibit #2 J. A. McManus, N. P." and also with my initials "E. T." which I have placed upon the card is a fair sample of the result of an attempt to lap weld two sheets by the process which involves the formation of small lakes of molten metal mentioned in the Hunter specification.

The accompanying exhibit marked "Rietzel Exhibit #3 J. A. McManus, N. P." and also with my initials "E.T." is a specimen of a lap welding made by forming initial projections at such distances apart that cold metal will be left between said projections and the union will be therefore by a line of separate welded points in contradistinction to the continuous welds made by using a large number of projections placed in close proximity to one another so that they will run into a continuous line of weld, in which case, however, a much greater amount of power will be required and if the attempt be made to allow rivers of melted metal to be formed the result would be a probable burning of the metal as shown in Exhibit #2.

My prior patent #396,015 discloses the use of rivets and makes mention of welding but the only possible welding that could be produced by that process would be possibly some sticking of the edge of the perforation in the metal sheet to the side of the rivet which is a mere incident of the invention and there is no welding of the superposed plane surfaces or opposed

faces of the plates to one another by welds disposed over such plane faces.

Elihu Thomson

DEPARTMENT OF THE INTERIOR

UNITED STATES PATENT OFFICE

WASHINGTON, D.C., December 14, 1908.
MAILED

Adolph F. Rietzel,

Care, Townsend & Decker,

141 Broadway, New York, N. Y.

Please find below a communication from the EXAMINER in charge of the application of your

for Method of Electric Welding, filed Feb. 24, 1905, Serial No. 247,081.

E. B. Moore
Commissioner of Patents.

In response to amendment of November 30, 1908.

Claim 1 is rejected as unpatentable over Benardos et al, 363,320, May 17, 1887, Class 219, Sub-class 15, or either of the French patents to Egel, 336,187, and 335,889, both in Class 219, Welding.

Claim 2 is objectionable because xf the expression "confining the flow of current to said spots" implies the use of apparatus such as a pointed electrode. The claim is therefore misleading as applied to the method described by the applicant. A similar objection is made to the expression "localizing the pressure in and confining the flow of current", in claim 4; "localizing the heating current", in claim 7; "confining the welding area of such current", in claim 8; and "confining the area of heating", in claim 14.

Claims 2 to 7, inclusive, are rejected on either of the French patents cited above.

Claims 9 and 11 are rejected as differentiating from Hunter of record only by a negative limitation.

Claim 17 is objectionable as an article claim inasmuch as the last portion of the claim beginning "that when the welding electric current etc" relates to the method of forming the article. A similar objection is made to claims 18, 19, 20 and 22.

Claims 16, 17, 18, 20, 21, 22 and 23 are rejected as presenting nothing patentable over Benardos, cited above, or either of the French patents cited above.

The article defined by claim 19 is not the article which would result from the process set forth in claims 4 and 8 and is a different species from the article defined by claim 23. Claim 19 defines an article in which the plane surfaces are not in contact, whereas in the article defined by claim 23 and resulting from the process set forth in claims 4 and 8 the plane surfaces are in contact. Restriction to a single species is therefore required.

--**--

In the matter of the application for patent of Adolph F. Rietzel, S. N. 247,081, filed February 24th, 1905, for Electric Welding:

AFFIDAVIT.

County of New York)
State of New York) ss:

ADOLPH F. RIETZEL, being duly sworn, deposes and says, that he is the applicant that filed the above entitled application for patent;

That prior to the 18th day of February, 1904, he repeatedly, successfully practised the method of fastening two sheets of metal together face to face by welding them at spots in their meeting surfaces by confining the heating electric current passed from one plate to the other in such spots and localizing the welding pressure at said spots, as claimed broadly in said application;

That the work of so uniting such sheets of metal was done at the factory of the Thomson Electric Welding Company at Lynn, Massachusetts, on a Welding Machine of a commercial type known as type 10 A Welder;

That said Machine was the same in construction as the machine known as type 5 A Welder but of larger size and was identical with that shown on the attached

page removed from a catalogue of the Thomson Electric Welding Company, which page is identified and marked "Page of Catalogue, D. M. Edsall, N. P.";

That the accompanying pieces of work marked "Specimen No. 1, D. M. Edsall, N. P." and "Specimen No. 2, D. M. Edsall, N. P." are duplicates of work so done by him on that Machine prior to the 18th day of February, 1904, but that the original specimens were not preserved;

That in doing such work he employed a pointed electrode, the same in form as the accompanying electrode marked for identification "Welding Electrode, D. M. Edsall, N. P.", which Electrode was clamped in one of the holders of the machine and was used to apply the localized pressure and heating current to the plates which were welded together at spots in their superficial area, the opposite or backing electrode being a block of metal which was flat and of a superficial area, approximating the area of the plates which were welded together and which opposite electrode was clamped in the opposite holder of the machine;

That in this operation the two plates superposed upon one another were inserted between said electrodes and the pressure and heating current localized as claimed were applied by forcing the pointed electrode against the outside face of the plates and pressing them between said pointed electrode and the opposite flat electrode, current being at the same time passed from one electrode to the other and pressure being applied by employing the usual devices forming a part of the machine and used in the ordinary operation of the machine for applying welding pressure to

the work;

That work was repeatedly and successfully done in this manner upon various sizes and pieces of metal plates, none of which however, are now in existence so far as affiant has been able to discover;

That the work done by him as aforesaid, demonstrated the complete success of the operation and that metal plates could be successfully and firmly united together by distinct or isolated electric welds forming welded spots of union in their meeting faces and constituting in effect a successful substitute for a union of the same by a number of rivets.

Adolph F. Rietzel

Page of Catalogue

SOME ADVANTAGES OF ELECTRIC WELDING.

1. **The Homogeneous Nature of the Weld:** When the weld is made, the structure of the metal at the joint *is the same* as elsewhere.

2. **Absolute Control Over the Heat:** By simple appliances the metal can be held at any temperature desired for any length of time, and the heat increased or decreased at will.

3. **The Welding Process can be Continually Watched:** The metal while heating is visible instead of being covered with coal or hidden by flame, as in the forge process.

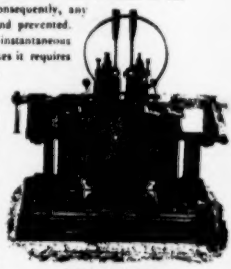
4. **Avoiding Flaws:** THE UNION COMMENCES AT THE INTERIOR OF THE JOINT, and not in an uncertain way; consequently, any possible flaw can be easily discovered and prevented.

5. **Rapidity:** The process is almost instantaneous with small sections, while with larger sizes it requires but little time, depending upon the horse-power used.

6. **Flexibility of the Process:** Applying as it does to various kinds and forms of metal, including those which have heretofore been united only by brazing.

7. **Accuracy:** The welds are kept in perfect line by the clamps during the operation.

8. **Localization of Heat at the Weld:** Consequently, no heating effect elsewhere.



9. **Cleanliness:** The apparatus can be used in any convenient or desirable place and makes no dirt or litter.

10. **No Blistering or Scaling:** The heat is confined to the welded joint.

11. **Lighting:** By using the necessary transformer, incandescent lamps can be used when the current is not required for welding purposes.

[redacted]: Simple and easy in operation; the current used in [redacted] render shocks, even of the slightest kind, impossible.

[redacted] labor and time; also, in material.

TYPE 34 WELDER Cover off.
For light irons, straight-away, angle or miscellaneous work.
Maximum Capacity, 30 [redacted] iron or steel.
Horse-power, 5 to 25 000 volts.
Approximate Weight 525 lbs.

Sir:

In the matter of the application of Adolph F. Rietzel for Composite Sheet Metal Structure, filed Feb. 24, 1905, S. N. 247,081;

Please amend as follows:

Erase paragraph beginning at the third line from the bottom on page 1 of the substitute specification filed November 24, 1908 and ending on line 2 of page 2, and substitute the following:

"Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots.

By the terms "weld" and "electric weld" as herein employed, I refer to that process of welding in which the metal is brought to plastic condition by passing an electric current from one to the other of two pieces where they are in contact and is welded while in such condition by the application of pressure, as contra-distinguished from a process of uniting metals, which is described in a Patent to Bernardos, No. 363,320, dated May 17, 1887, and in which the union is effected by melting the metal by an arc

P' and which is different from "welding" in the ordinary sense of the term as applied to metal manufactures, in that the metal is heated beyond the point of plasticity and pressure is not employed."

Erase beginning with line 13, page 2, to the end of line 23, same page and substitute:

P² "A weld formed according to my invention is distinguished however from such prior welds by the fact that the opposed surfaces are welded together in spots only, theheating electric current being localized or confined in any desired way to such spots so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together."

Erase claim 1 and substitute:

P³ "1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots."

In claim 2, before "passing", line 5, insert: "and".

Line 6, same claim, erase the word "and" and substitute: "while".

Claim 4, line 5, erase the word "and" before the word "localizing" and substitute: "while",

Claim 4, line 4, before "passing" insert "and".

In claim 4 erase the words "and the areas immediately surrounding the same".

To claim 6 add the following: "completely surrounding said spot".

In claim 7, before "passing", line 5, insert "and".

In claim 7, line 6, change "and" to "while".

In claim 8, line 5, erase the word "and" to gether with the comma immediately preceding the same and substitute: "while".

In claim 8 erase the words "and the areas immediately surrounding the same".

In claim 9 erase the words "will not extend into one another from one spot to the next" and substitute: "will be separated from one another by unwelded areas".

In claim 11 erase the words "spots separated by well defined areas of no welding" and substitute: "isolated spots".

Before the word "spots", line 9, claim 11, insert "contact".

In claim 14 after the word "spot", line 9, insert "entirely surrounded by unheated areas".

Erase claim 16 and substitute:

E5 Erased Per F

"16. "Composite metal work having its component pieces welded together in spots onlyon their opposed or meeting surfaces and by pressure applied at said spots while in plastic condition, thus producing a union of the metal in spots separated from one another by distinct areas which are unwelded, as and for the purpose described."

Erase claim 17 and substitute:

E6 F P

16 "17. "Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting backs portions of the metal plates, the back of said unaltered in their metallic condition plates being practically unaffected and the spots on the meeting surfaces being separated from one another by distinct unwelded areas".

Erase claim 18 and substitute:

E7 Sub. F3

"18. Metal plates arranged face to face and fastened together on their plane surfaces by a number of distinct or isolated pressure formed electric welds involving metal of said plates heated to welding temperature on their meeting sides only and at spots on said surfaces separated from one another by distinct surrounding areas of unwelded metal, as and for the purpose described."

In claim 20, after "plates", line 4, insert:

E8 Per F

"heated to the welding temperature on the meeting portions or surfaces of said plates only".

Erase claim 21 and substitute:

E9 Per F

"21. Composite metal work comprising superposed plates secured together by an electric weld-

sur
ing of the same on their opposed faces by distinct spots of welded union formed by pressure and reduction of the metal at such spots to plastic condition, said spots being isolated or separated from one another by distinct surrounding areas unwelded on such meeting faces."

In claim 22, line 2, erase the words "welded to one another on their opposed faces" and substitute: "welded by the material of their opposed faces only reduced to welding temperature and".

Per F

Erase claim 23 and substitute:

"23. Metal plates electrically welded together by heating current and pressure located in a spot or spots involving the material of their opposed or meeting portions and surrounded by distinct areas of unwelded union, as and for the purpose described."

"24. Sheet metal plates electrically welded together by heating current and pressure at a spot or spots definitely located in and involving the heated material of the opposed or meeting portions of the plates entirely surrounded by distinct areas unwelded, as and for the purpose described."

At the end of the specification insert the following:

"The product of the foregoing process is readily distinguishable from that produced by an electric arc applied at the back of two plates to be joined as proposed in the before mentioned patent of Bernardos by the fact that in my improved product there is no burning of the metal on the back

of the plate and the back surface will not be marred but will, when the process is properly conducted, retain a smooth finish, particularly adapting the work for subsequent enameling. The improved product also possesses the advantage, when applied to the sheet metal, that the spots of welding being located within the edges of the meeting surfaces will not show and will not mar the finish of the completed work. The product is also superior to that produced by a riveting of the plates in that there are no rivet heads to mar the finish of the back or outer surface of the metal".

B12

REMARKS:

We file herewith an affidavit establishing completion of the invention on applicant's part prior to the dates of the French patents cited by the Examiner in his last official letter.

The formal amendments to the method claims are those which were agreed upon at the conference with the Examiner on the 26th ultimo, and as we understand, remove the objections raised by the Examiner.

The terms used by applicant are broad and intended to be broad and define the process in the broad terms commensurate with the extent of the invention and they cannot be held to be misleading because they may be of such scope as to cover variations of the broad process claimed. There may be still negative expressions in some of the claims but they are not used in a way that we think can be

held to be objectionable for they express in the most direct and clearest manner possible one of the essential differences between applicant's process and the Hunter process. For instance, in Hunter there are no unwelded areas between the initial contact spots and this is one of the characteristic differences best expressed it seems to us in the terms that have been employed.

Applicant has claimed not only the process but the product of that process. The process is unquestionably different from that of Bernardos which, as stated to the Examiner in the course of the interview referred to, is not a true welding process, inasmuch as it involves the reduction of the metal to fluidity instead of simply to plastic condition, and does not employ pressure.

The term "welding" is not used by the patentee at all, and we presume advisedly. It would seem that there are some publications in which the Bernardos process is spoken of as a welding process. The term "welding", so used, is unquestionably a misnomer. In order that, however, there may be no ambiguity in regard to what applicant claims as his invention we have inserted the above reference to the Bernardos patent which makes the distinction obvious and operates as a disclaimer.

The improved product resulting from applicant's process is readily distinguishable by simple inspection from anything that could be produced by the Bernardos arc process. In that process there is necessarily a burning of the outside surfaces of the metal for the arc is applied to the outside,

the heat is localized on the outside, and the melting of the plates on their meeting surfaces can only take place when the fluid condition produced by the arc is extended through the whole body of the metal to the inner surface. There is naturally a burning and roughening of the metal on the outer surface which mars the finish and makes it apparent that the arc process has been used. No such marring and burning exist in applicant's product and to one skilled in the art it would be manifest that the product has resulted from the essential process claimed and recognized by the Examiner as a patentable process. The improved product of the improved process being clearly distinguishable as a product from, and manifestly superior to that of Bernardos, it is clear that the product as well as the process claimed should be allowed.

Respectfully submitted,

Adolph F. Rietzel

Please find below a communication from the EXAMINER in charge of the application of your

for Method of Electric Welding, filed Feb. 24, 1905, Serial No. 247,081.

c4—981

E. B. Moore
Commissioner of Patents.

In response to communication of March 13, 1909.

The word "spot" does not occur in line 9 of claim 14; consequently the matter which the applicant has directed to be inserted after the word "spot" in line 9 of claim 14 has not been entered. Inasmuch as claim 14 has not been amended, the objection to this claim, made in the third paragraph of the office letter of Dec. 14, 1908, has not been overcome, and this objection is repeated.

In claims 16 and 18 to 24, inclusive, the article is defined at least partly by themethod of making it. These claims are therefore objectionable.

In line 4 of claim 17, should not "back" be changed to backs?

Throughout the prosecution of this case the more specific claims have read only on Fig. 2 (see claim 7 of the original specification and see present claim 15). The applicant will therefore not be permitted to retain in the case article claims which will not read upon the article produced by the process illustrated in Fig. 2. It is not believed that claim 17 will read upon the article produced by the method illustrated in Fig. 2 because it does not appear that the backs of the plates would be unaffected in this process. The cancelation of claim 17 is therefore required.

In claim 19 it is not clear what the following phrase refers to, viz. "comprising raised electric contact spots etc.".

The language of claim 19 implies that the plane surfaces of the metal of the plates are not in contact. Therefore the article defined by this claim will not result from the processes set forth by some of the other claims in the case, e. g. claims 4 and 8, in which it is specified that the plane surfaces of the metal plates meet. This claim is also alternative to claims 16, 17 and 18. Restriction to a single species is required.

The word "reduced" in the phrase "reduced to welding temperature" in the insertion in line 2 of claim 22 is evidently an inappropriate term.

U.S. PATENT OFFICE APPLICATION ROOM Serial No.247,081 Paper No.23
MAY 7 1909 MAY 7 1909
DIVISION 26 U.S.PATENT OFFICE "P"

New York, May 6th, 1909.

Hon. Commissioner of Patents,

Washington, D. C.

Sir:

In the matter of the application of Adolph F. Rietzel for Uniting the Component Parts of Composite Sheet Metal Structure, filed February 24, 1905, S. N. 247,081;

In reply to the Examiner's letter dated April 9, 1909, please amend as follows:

Erase matter inserted by the last amendment at the end of the specification and substitute the following:

"The product of the foregoing process is readily distinguishable from that produced by melting down the metal of the pieces from the back at spots as proposed in the before mentioned patent of Bernardos in that there is no substantial alteration of condition of the metal back of the welds appearing as a burning, roughening or disintegration of the material by the very great heat of the electric arc employed for melting down the metal, and by the further fact that the unions themselves in the material of the juxtaposed or opposite faces have the characteristics of a true weld produced by bringing the metal to welding temperature only and applying pressure, so that the pieces are solidly and firmly united and cannot be readily torn apart as they could be if the metal at the spots has been melted down under

the high temperature of the electric arc.

"The product in the form of sheet metal is further particularly useful for sheet metal ware since the outer or exposed surface of the metal will have the smooth and practically unaltered finish of sheet metal and said surface will not be substantially marred when the process is properly conducted, excepting for the presence of such infrequent small depressions as might remain from the previous indentation of the metal from the back when, as hereinbefore described, an indenting of the metal may be resorted to.

"The product in sheet metal also possesses the advantage that the spots of welding when being located within the edges of the meeting surfaces ~~or each entirely surrounded by unwelded areas~~, will not show. The produce is also superior to that produced by riveting of the plates in that there are no rivet heads to mar the finish of the back or outer surfaces of the metal."

Erase "separated from one another" in claim 5, line 8, and substitute "entirely surrounded".

In claim 8, line 8, erase "between" and substitute "around".

In claim 14 l. 3 change "point" to "points"

In claim 14, line 8, after the word "spot" first occurrence insert "entirely surrounded by areas unheated to welding temperature".

In claim 14, l. 8 cancel "point or"

Erase claim 16.

In claim 17 erase the word "unaffected", line 8, and substitute "unaltered in their metallic

condition". In line 4 of the same claim change the word "back" to "backs".

Change the ordinal of claim 17 to 16.

Erase claims 18 to 24 inclusive and substitute:

"17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

"18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

"19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described."

REMARKS:

The applicant, by the foregoing, has confined his claims to the product to four claims each of which, it is thought, clearly avoids the technical objection raised by the Examiner and an immediate allowance is respectfully requested.

Respectfully submitted,

A. F. Rietzel

DEPARTMENT OF THE INTERIOR

UNITED STATES PATENT OFFICE

Adolph F. Rietzel, Assor. WASHINGTON, D.C., June 24, 1909.
% Townsend & Decker,
#141 Broadway, New York, N. Y.

Sir: Your APPLICATION for a patent for an IMPROVEMENT in Uniting the Component Parts of Composite Sheet Metal Structures, filed Feb. 24, 1905 has been examined and ALLOWED.

The final fee, TWENTY DOLLARS, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent on this application will be withheld, unless renewed with an additional fee of $15, under the provisions of Section 4897, Revised Statutes.

The office delivers patents upon the day of their date, and on which their term begins to run. The printing, photolithographing, and engrossing of the several patent parts, preparatory to final signing and sealing, will require about four weeks, and such work will not be undertaken until after payment of the necessary fee.

When you send the final fee you will also send, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR and TITLE OF INVENTION AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If you desire to have the patent issue to ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of final fee.

After issue of the patent uncertified copies of the drawings and specifications may be purchased at the price of FIVE CENTS EACH. The money should accompany the order. Postage stamps will not be received.

Final fees will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

Respectfully,

E. B. Moore.

Commissioner of Patents.

IN REMITTING THE FINAL FEE GIVE THE SERIAL NUMBER AT THE HEAD OF THIS NOTICE.

Adolph P. Rietzel, (Assor to Thomson Electric Welding Company, of Lynn, Mass., a corp, of Maine.)

c/o Townsend & Decker,

141 Broadway, New York City.

Please find below a copy of a communication from the Examiner concerning your application for "Uniting the Component Parts of Composite Sheet Metal Structures", filed Feb. 24, 1905, Serial No. 247,081, Pat'd July 20, 1909, Patent No. 928,701.

Very respectfully,

Room No. 105.

All communications should be addressed to "The Commissioner of Patents, Washington, D. C."

E. B. Moore

Commissioner of Patents.

31792

Your case, above referred to, is adjudged to interfere with others, hereafter specified, and the question of priority will be determined in conformity with the Rules.

The statement demanded by Rule 110 must be sealed up and filed on or before the 27 *day of* JUN 1910 *, 190..., with the subject of the invention, and name of party filing it, indorsed on the envelope. The subject-matter involved in the interference is*

INVENTION.

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

3. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

4. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

5. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only,

each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

6. Composite material work having its component pieces welded together in spots only involving the material of their opposed contacting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

7. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

8. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

The interference involves your patent above identified, and

An application for "Electric Welding", filed by Johann Harmatta, whose post office address is Szepesvaralja, Hungary, and whose attorneys are O. E. Duffy & Son, of 612 F Street, N. W., Washington, D. C.

The relation of the counts of the interference to the claims of the respective parties is as follows:

Counts:	Rietzel:	Harmatta:
1	1	2
2	5	3
3	6	4
4	16	5
5	17	6
6	18	7
7	19	8
8	20	9

If the interference is decided against Harmatta all the claims now in the case will be rejected as not patentable over the issue.

#31792.

Please find below a communication from the EXAMINER in charge of the application of your

247,081, filed Feb. 24, 1905:----

Method of Electric Welding.

21792

E. B. Moore.
Commissioner of Patents.

6--9631

The following counts have been added to the above entitled interference:----

9. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

10. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

11. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

The preliminary statement required by Rule 110, as to the added counts only, should be filed on or before AUG 14 1911

The relation of the added counts of the interference to the claims of the respective parties is as follows:---

U.S.PATENT OFFICE

Hon. Commissioner of Patents,

Washington, D. C.

DISCLAIMER.

Your Petitioner, the Thomson Electric Welding Company, a corporation organized and existing under the laws of the Commonwealth of Massachusetts, respectfully represents:

That your Petitioner, the Thomson Electric Welding Company, is the present owner of United States Patent No. 928,701, for Uniting the Component Parts of Composite Sheet Metal Structures, issued July 20th 1909, to the Thomson Electric Welding Company, a corporation duly organized under the laws of the State of Maine as assignee of Adolph F. Rietzel;

That your Petitioner has reason to believe that through inadvertence, accident or mistake, and without any fraudulent or deceptive intention, the patentee, in said Letters Patent, has claimed more than that of which he was the original or first inventor or discoverer.

Your Petitioner therefore hereby enters its disclaimer to that part of the invention described in said patent which is set forth in the specification in the following words:

> "Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots."

except when that process is carried out by the preferred method of providing conducting projections or points be-

tween the meeting surfaces of the pieces to be united;

and its disclaimer to that part of the claim in the specification which is in the following words:

"1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

"2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

"3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and theheating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

"4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

"5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

"6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

"16. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

"17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

"18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union andthe portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

"19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

"20. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points."

In Testimony Whereof your Petitioner has caused these presents to be signed by its President and its corporate seal to be affixed this 1st day of June, 1915.

UNITED STATES PATENT OFFICE.

ADOLPH F. RIETZEL, OF LYNN, MASSACHUSETTS, ASSIGNOR TO THOMSON ELECTRIC WELDING COMPANY, OF LYNN, MASSACHUSETTS, A CORPORATION OF MAINE.

UNITING THE COMPONENT PARTS OF COMPOSITE SHEET-METAL STRUCTURES.

No. 928,701. Specification of Letters Patent. Patented July 20, 1909.

Application filed February 24, 1905. Serial No. 247,081.

To all whom it may concern:

Be it known that I, ADOLPH F. RIETZEL, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, (with post-office address Lynn, Massachusetts,) have invented certain new and useful Improvements in Uniting the Component Parts of Composite Sheet-Metal Structures, of which the following is a specification.

My invention relates to the manner of uniting or fastening two pieces of metal to one another and its object is more particularly to afford a substitute for the manner of uniting pieces of metal as heretofore practiced in the art of electric welding.

As applied to sheet metal manufactures the object is to afford a cheap and practical substitute for riveting and other methods of mechanically securing the two pieces of metal together. As applied to this branch of the metal working arts, the invention affords a means whereby articles of composite sheet metal manufacture may be made up by fastening the pieces of metal constituting the structure with a perfectly secure union and by a process that can be economically conducted.

Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots.

By the terms "weld" and "electric weld", as herein employed, I refer to that process of welding in which the metal is brought to plastic condition by passing an electric current from one to the other of two pieces where they are in contact and is welded while in such condition by the application of pressure, as contra-distinguished from a process of uniting metals, which is described in a patent to Bernardos, No. 363,320, dated May 17, 1887, and in which the union is effected by melting the metal by an arc and which is different from "welding" in the ordinary sense of the term as applied to metal manufactures, in that the metal is heated beyond the point of plasticity and pressure is not employed.

It has been before proposed to electrically weld two rods of metal together by a butt-welding process, the area of union effected being substantially coextensive with the cross-section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces. It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces. A weld formed according to my invention is distinguished however from such prior welds by the fact that the opposed surfaces are welded together in spots only, the heating electric current being localized or confined in any desired way to such spots so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together.

My invention is particularly valuable in fastening of pieces of sheet metal together because not only does it limit the amount of electric energy required very considerably as compared with the prior methods of union, but it also diminishes the liability to burning of the metal which is liable to occur when the attempt is made to form a union of two sheets of metal by an electric welding process over substantially the whole area of the meeting or opposed surfaces.

In carrying out my invention any desired number of spots of union may be employed, such number depending obviously upon the extent of the meeting surfaces which are to be fastened together and also upon the strength of the union desired.

In carrying out my invention the localization of the flow of heating electric current and of welding pressure to the desired spot or spots may be brought about in any desired way. One of the preferred ways is by providing between the meeting surfaces or portions of the pieces to be united suitable conducting projections or points at the spots of union, which projections or points carrying the heating electric current from one piece to the other are so located in the meeting surfaces and are so separated from one another that on the application of the weld-

ing pressure the welded union resulting will be localized in the area of the opposed surfaces and will be substantially coextensive in area with the restricted area of the path of the effective heating current. Various ways of providing such points or projections will occur to those skilled in the art.

The preferred method is to indent the metal from the side reverse to that on which the union is effected by a suitable tool, the projections thus formed affording points for the passage of the electric current. This method is preferable also because it permits the welding to be produced at a multiplicity of spots simultaneously through the application of pressure over the whole rear surface of the plate, the points or projections in that case serving not only to localize the flow of the heating current but also to localize the welding pressure.

In the preferred manner of carrying out my invention in the case of sheet metal manufacture I provide projections from the meeting surfaces of both pieces that are to be united. Said projections may also be provided by interposing between the two plane sheets small pieces of conducting material which act in the same manner when the sheets are brought together, as projections which localize the heating current and the pressure. It will be understood, however, that in the latter instance as in the former, these pieces are so small and are placed such a distance apart that on the application of welding pressure there will be no running of the ...elds into one another but that the final union will be in spots only leaving well-defined areas on the meeting surfaces, in which the surfaces either lie in contact or separated from one another by a very thin space.

From the foregoing it will be seen that my invention is distinguished from prior methods of welding pieces of metal together in that it may be very cheaply practiced, because no attempt is made to weld over the whole of the opposed surfaces of the welded pieces; but on the contrary the union is at a spot or spots only which in ordinary cases will afford as strong a union as would be produced by the riveting of the pieces.

The invention further has the advantage that not nearly so much electric energy is required as is necessary when the electrically welded union extends over the whole area of the opposed surfaces. Moreover, the danger of burning when the attempt is made to weld two sheets of metal together by a lap weld is largely eliminated.

In the accompanying drawings Figures 1, 2, 3, 4 and 5 illustrate some of the ways in which the pieces of metal to be united may be prepared for the welding according to my invention. Figs. 6, 7, 8, and 9 show modifications in the form and disposition of the contact projections which result in the spots of electrically welded union. Fig. 10 shows the assembling of three plates together for welding according to my invention.

In the various figures of the drawing the invention is illustrated as carried out with two sheets of metal B. B'. In Fig. 1, plate B'. only is provided with the distinct or isolated spots (c) or projections for the flow of the electric current, to the plate B. which spots or points may be formed by indenting the plate with a suitable tool. The spots are located so far from one another that on the application of pressure coincidently with the flow of electric current from one plate to the other there will be a number of distinct areas or spots of electrically welded union of the plates separated by well-defined areas on the meeting surfaces in which no union takes place. The resultant is however a fastening of the plates together securely and which is practically as effective as if the attempt were made to form a welded union over the entire areas of the meeting surfaces. Obviously, the greater the distance between the spots the lesser the number that would be used and hence the lesser the consumption of energy in effecting the weld. This is of considerable importance where the meeting areas are large or where a considerable amount of work has to be done. The welding pressure is conveniently applied by conducting-blocks or electrodes, A, A', between which the two pieces B, B', are assembled. These electrodes, A, A', furnish the heating current while applying the pressure, the localization of the pressure in the spots being brought about in this instance by the pointing of the surfaces at point c.

In Fig. 2 both plates are provided with projections the points of which engage with one another, the pointing being produced by indenting the metal sheets from the rear.

Fig. 3 illustrates the localization of the welding by casting projections upon one of the sheets and Fig. 4 by casting projections on both pieces. The localization of the welding in spots might be effected as illustrated in Fig. 5 by interposing small pieces of metal at the spot or spots of desired union, these pieces operating when the plates are brought together in the same way as the projections before referred to. The number and size of the pieces and their distance apart is in this case, as before, so chosen that the application of pressure together with the flow of heating current from one plate to the other will result in a union of the two pieces over their opposed surfaces in spots only thereon.

Fig. 6 shows how the spots might be disposed to fasten the pieces together in distinct spots around their edges.

As shown in Figs. 7 and 8 the projections, instead of being round, might be somewhat elongated and irregularly or symmetrically arranged.

Fig. 9 shows round and somewhat elongated projections combined.

In all these instances however, the union over the surfaces of the plates is confined to spots or areas which are of comparatively small extent as compared with the total area of the meeting surfaces. As will be obvious, the form and disposition of the points or projections of initial contact for flow of the electric current and localization of the pressure may be greatly varied without departing from my invention.

Fig. 10 illustrates the welding of three plates of sheets together when superposed.

My invention is especially useful in the manufacture of articles from sheet metal which are stamped out to different forms, and which have heretofore had their component portions united by riveting or other purely mechanical expedient which is not only expensive but requires generally special tools and results in many cases in an insecure union. When the invention is employed in its preferred form or manner of practice in the field of sheet metal manufacture all that is necessary is to provide the contact spots or projections as already described and then to assemble the pieces in an electric welding machine and weld them together as already set forth.

The product of the foregoing process is readily distinguishable from that produced by melting down the metal of the pieces from the back at spots as proposed in the before mentioned patent of Bernardos in that there is no substantial alteration of condition of the metal back of the welds appearing as a burning, roughening or disintegration of the material by the very great heat of the electric arc employed for melting down the metal, and by the further fact that the unions themselves in the material of the juxtaposed or opposite faces have the characteristics of a true weld produced by bringing the metal to welding temperature only and applying pressure, so that the pieces are solidly and firmly united and cannot be readily torn apart as they could be if the metal at the spots has been melted down under the high temperature of the electric arc.

The product in the form of sheet metal is further particularly useful for sheet metal ware since the outer or exposed surface of the metal will have the smooth and practically unaltered finish of sheet metal and said surface will not be substantially marred when the process is properly conducted, excepting for the presence of such infrequent small depressions as might remain from the previous indentation of the metal from the back when, as hereinbefore described, an indenting of the metal may be resorted to.

The product in sheet metal also possesses the advantage that the spots of welding when located within the edges of the meeting surfaces will not show. The product is also superior to that produced by riveting of the plates in that there are no rivet heads to mar the finish of the back or outer surfaces of the metal.

What I claim as my invention is:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

5. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and, simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

7. The method of welding two pieces of metal together, consisting in superposing said pieces with their surfaces at which the union is to take place superposed or pre-

sented to one another, pressing the pieces together, and passing a heating electric current from one to the other while localizing the heating current simultaneously in a number of distinct or separate spots of limited area, separated from one another sufficiently to secure a union of the pieces in a number of corresponding distinct spots surrounded by and separated from one another by distinct areas in which no union exists.

8. The method of uniting two pieces of metal, consisting in providing between their meeting surfaces a number of projections, spaced apart as described, pressing the pieces together and passing an electric current through said projections while confining the welding area of such current to said projections so as to leave distinct areas around spots in which no welding shall be produced.

9. The method of fastening two plates of metal together at a multiplicity of distinct or separate points of welded union, consisting in providing between them a number of isolated contact spots adapted to pass an electric current from one to the other but so separated that the electric welds will be separated from one another by unwelded areas, passing a heating electric current through such spots simultaneously and applying pressure as and for the purpose described.

10. The herein described method of electrically welding two plates or sheets of metal of any gage together by distinct spots of union disposed over their plane surfaces, consisting in providing a multiplicity of electrical contact spots coincident with the separated spots of union and disposed at such distances apart that there will be well-defined areas between spots through which the electric current will not flow, passing electric current from one plate to the other through said contact spots simultaneously and applying pressure as and for the purpose described.

11. The method of fastening two sheets of metal together, consisting in providing between them a number of isolated contact spots for the passage of the electric welding current, said spots being adapted to initially hold the plates apart and being separated from one another a sufficient distance to confine the welding to distinct areas or isolated spots, passing a heating electric current through a number of said contact spots simultaneously and pressing the plates together as and for the purpose described.

12. The method of fastening two plates of metal together, consisting in furnishing a surface of said plates with a number of projecting contact spots for the passage of welding electric current and disposed at such distances apart that on the application of pressure the welds will not run into one another, superposing said plates, passing a heating electric current from one to the other over said separated spots and applying the pressure to produce a spot-welding of the plates to one another as and for the purpose described.

13. The herein described method of fastening two pieces of metal together by providing each plate with a number of projecting contact spots on its plane surface disposed at such distances apart that the unions will not run into one another but will, nevertheless, firmly hold the plates together, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other through the spots and simultaneously applying pressure thus uniting the plates at a number of distinct points of welded union.

14. The method of uniting two sheets of metal face to face, consisting in indenting the material, superposing the plates with the points of the indentations engaged, passing an electric current from one plate to the other through said points simultaneously, and applying pressure while confining the area of heating to welding temperature to a circumscribed area or spot entirely surrounded by areas unheated to welding temperature to unite the pieces in a distinct spot or spots of small extent in the whole area of the opposed faces.

15. The herein described method of fastening two plates together at a multiplicity of distinct mechanically separated points of welded union, consisting in indenting each plate to form a number of projecting contact spots on the plane surfaces which are to abut, superposing said plates with the projecting spots in simultaneous engagement with one another, passing a heating electric current from one plate to the other thereby forming a number of distinct zones or points of heated metal, heated to welding temperature, and applying pressure to complete the union of plates by a number of mechanically distinct unions.

16. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

20. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

Signed at Lynn in the county of Essex and State of Mass. this 7th day of Feb. A. D. 1907.

UNITED STATES PATENT OFFICE.

To All whom these presents shall come, Greeting:

THIS IS TO CERTIFY that the annexed is a true copy from the records of this Office of the File Wrapper and Contents, in the matter of

INTERFERENCE No. 31,792.

RIETZEL

vs.

HARMATTA.

Subject-Matter:—

ELECTRIC WELDING.

IN TESTIMONY WHEREOF I have hereunto set my hand and caused the seal of the Patent Office to be affixed at the City of Washington, this 14th day of September, in the (Seal) year of our Lord one thousand nine hundred and seventeen and of the Independence of the United States of America the one hundred and forty-second.

R. F. WHITEHEAD,
Acting Commissioner of Patents.

ELECTRIC WELDING.

DIVISION 15.

2—251. Letter No. 227.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE,

WASHINGTON, D. C.,

April 14, 191 .

Examiner of Interferences:

An interference is found to exist between the following cases, and in respect to the invention therein specified, to wit:

CASES.

1. Name Adolph F. Rietzel.
   Post-office address Lynn, Massachusetts.
   Title Uniting the Component Parts of Composite Sheet Metal Structures.
   Filed Feb. 24, 1905. Ser. No. 247,081. Pat'd July 20, 1909. No. 928,701.
   Attorneys Townsend & Decker, of 141 Broadway, N. Y. City
   Assignee Thomson Electric Welding Co., of Lynn, Mass.
2. Name Johann Harmatta.
   Post-office address Szepesvaralja, Hungary.
   Title Electric Welding.
   Filed Dec. 3, 1903. Ser. No. 183,677.
   Attorneys O. E. Duffy & Son, of 612 F St., N. W., Washington, D C.

Intf. Number 31792
Intf. Declared Apr 26 1910
Statements Due 27 Jun 1910.
(For redeclaration see paper No. 48.)

6—2610

INVENTION.

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The method of uniting two sheet metal pieces together face to face, consisting in pressing them together, and simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by areas of no union.

3. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

4. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas.

5. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

6. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.

7. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described.

8. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points.

The relation of the counts of the interference to the claims of the respective parties is as follows:

Counts:	*Rietzel:*	*Harmatta:*
1	1	2
2	5	3
3	6	4
4	16	5
5	17	6
6	18	7
7	19	8
8	20	9

If the interference is decided against Harmatta all the claims now in the case will be rejected as not patentable over the issue.

(Counts compared.) A. P. SHAW, *Ex.*

In re Interference:

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

No. 31,792. W.

("W" in margin.)

PRELIMINARY STATEMENT OF ADOLPH F. RIETZL.

County of New London, State of Connecticut, ss:

ADOLPH F. RIETZEL of Charlestown, County of Washing-

ton and State of Rhode Island, being duly sworn, doth depose and say that he is a party to the interference declared by the Commissioner of Patents on the 26th day of April, 1910, between the patent of Adolph F. Rietzel, No. 928,701, dated July 20th, 1909, and an application for a similar invention filed by Johann Harmatta;

That he conceived the invention set forth in the declaration of interference during the latter part of October or first part of November, 1897;

That, as near as deponent can at this time fix the date, the invention was successfully reduced to practice in the latter part of July 1898, and at the same time was first explained and disclosed to others;

That sketches of the application of the invention were made in the early part of June 1904 and from time to time since that date innumerable sketches have been made of the invention as applied to various articles of manufacture;

That the invention has been put to very extensive use in the manufacture of numerous sheet and other metal work of various kinds.

ADOLPH F. RIETZEL.

Sworn to before me this 7 day of June, 1910.

ALBERT S. MARTIN,
Notary Public.

INTERFERENCE IN THE UNITED STATES PATENT OFFICE.

J. HARMATTA

vs.

A. F. RIETZEL.

No. 31,792.

PRELIMINARY STATEMENT OF JOHANN HARMATTA.

Johann Harmatta, Engineer, a subject of the King of Hungary, residing at Szepesvàralja, in the Kingdom of Hungary, being duly affirmed, deposes and says that he is a party to the interference declared by the Commissioner of Patents on April 26th, 1910, between his application for patent of the United States, filed December 3rd, 1903, serial number 183,677, for *"Improvements in Electric Welding"*, and the patent to Adolph F. Rietzel, of Lynn, Massachusetts, granted July 20th 1909, numbered 928,701, for

"Uniting the Component Parts of Composite Sheet-Metal Structures"; that he conceived the invention set forth in the declaration of interference at the end of the year 1900, without having had then the opportunity of carrying out said invention for lack of time; that on or about the 15th day of September 1901, as he set working his own manufactory at Szepesváralja, he first made drawings of the device for carrying out the process set forth in the claims involved in the interference; that in the first days of October 1901 he modified an old chain-welding machine so as to be able to carry out said process as set forth in the claims involved in the interference; that on the 15th of to the 20th day of October 1901, he had thin iron sheets welded and attachments welded upon sheet metal vessels successfully and on a manufacturing scale by his workmen Michael Hozza and Michael Tomaskiewicz, with the help of the process forming the object of the claims involved in the interference; said two workmen, which live here at Szepesváralja and which remember very well to have performed the said work at the mentioned time, being ready to give testimony in respect of the above facts; that in the course of November 1901 he mentioned said electric weldings of thin iron sheets to Mr. Hegenscheidt, Director General of the firm "Oberschlesische Eisenindustrie A. G." (Upper Silesian Iron Industry Company of share-holders) at Gleiwitz, Silesia, Germany, in the presence of the Chief-Engineer of said Mr. Hegenscheidt, Mr. Wilhelm Fischer, which is at present Director, and that said gentleman promised to inform the firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz, Silesia, Germany, about the said electric weldings of thin iron sheets; that the firm "Eisenhütte Silesia" received said information from said gentlemen, but raised doubts about the possibility of electrically welding such thin iron sheets without danger of burning through said metal sheets; that said firm "Eisenhütte Silesia", for the sake of verification, sent during the summer of the year 1902, to him (Harmatta) several blanks of sheet metal utensils, which he (Harmatta) welded, with the help of the process forming the object of the claims involved in the interference, to the thorough satisfaction of said "Eisenhütte Silesia", that then Mr. Schweisfurth of Paruschowitz, technical Director of the firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz, Silesia, Germany, came to him in order to look at the electric weldings and the modified chain-welding machine; and, as said Mr. Schweisfurth had convinced himself by ocular proof that it is very easy to weld such thin iron sheets with the help of the process forming the object of the claims involved in the interference, the said firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschwitz acquired the property of said process by a contract made with him (Harmatta) at the date of February 12th, 1902, and that from the month of January 1903 a great number of full-size machines adapted to carry out the welding process forming the object of the claims involved in the interference have been manufactured by said "Eisenhütte Silesia" for personal use and sale to others; the first new and full-

size machine of this kind having been completed in the last days of January 1903 and first successfully operated and used in February 1903 for carrying ou. his process, in the works of the "Eisenhütte Silesia", in the village of Paruschowitz, Silesia, (Germany).

That patents for such invention were applied for and obtained as follows:

Application filed in Germany, March 24th, 1903, published June 20th, 1904, patent not granted;

application filed in Sweden, October 12th, 1903, patent dated October 12th, 1903, No. 24035; published the 16th day of November 1907 and granted the 23rd day of January 1908;

application filed in France, October 13th, 1903, patent dated October 13th, 1903, No. 336187; published the 1st Day of March 1904 and granted the 7th day of January 1904;

application filed in Austria, October 14th, 1903, patent dated August 1st, 1905, No. 24335; published the 8th day of January 1905 and granted the 30th day of March 1906;

application filed in Denmark, October 14th, 1903; published May 16th, 1905, patent not granted;

application filed in Luxemburg, October 14th, 1903, patent dated October 15th, 1903, No. 5300; published the 14th day of October 1903 and granted the 14th day of October 1903;

application filed in Hungary, October 15th, 1903, patent dated October 15th, 1903, No. 31382; published the 29th day of April 1904 and granted the 24th day of August 1904;

application filed in Switzerland, October 15th, 1903, patent dated October 15th, 1903, No. 29723; published June 21st, 1905 and granted the 21st day of June 1905;

application filed in Belgium, October 16th, 1903, patent dated October 16th 1903, No. 173119; published the 20th day of January 1904 and granted the 31st day of October 1903;

application filed in Russia, October 20th, 1903, patent not granted;

application filed in Spain, October 20th, 1903, patent dated December 10th, 1903, No. 32726; published the 10th day of December 1903 and granted the 10th day of December 1903;

application filed in Italy, October 22nd, 1903, patent dated October 22nd, 1903, No. 180/117; published the 16th day of December 1903 and granted the 16th day of December 1903;

application filed in Great Britain, October 23rd, 1903, patent dated October 23rd, 1903, No. 22981/1903; published the 20th day of October 1904 and granted the 25th day of August 1904;

application filed in Canada, December 4th, 1903, patent not granted;

application filed in Canada, December 4th, 1903, patent not granted;

application filed in Japan, December 14th, 1903, patent dated April 6th, 1905, No. 8640; published the 6th day of April 1905 and granted the 6th day of April 1905;

application filed in Romania, July 11th, 1906, patent not granted.

That such invention was fully described in the following patent specifications; Sweden No. 24035; France No. 336187; Austria No. 24335; Hungary No. 31382; Switzerland No. 29723; Great Britain No. 22981/1903; Japan No. 8640.

The knowledge of such invention was first introduced in the United States on December 3rd, 1903 by the papers belonging to said U. S. application of Harmatta, serial number 183,677, for "Improvement in Electric Welding", filed December 3rd, 1903, said application papers having been sent by applicant to Messrs. Marion & Marion at Montreal, Canada, who filed said application to the United States Patent Office on December 3rd, 1903.

BEFORE THE EXAMINER OF INTERFERENCES.

In re Interference:

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

No. 31,792.

AFFIDAVIT.

CHAS. F. TISCHNER, Jr., being duly sworn, deposes and says, that he is a member of the firm of Townsend & Decker, 149 Broadway, N.Y., the attorneys of record for the party Rietzel in the above Interference; that on the 5th day of July, 1910, said firm received a communication by mail from the Examiner of Interferences dated July 2, 1910, the date of mailing and which was a Saturday, stating that the preliminary statements of the parties in the above Interference were approved and setting times for taking testimony; that on that day, namely July 5th, the said firm ordered from the Commissioner of Patents a certified copy of the file wrapper, contents and drawings of the application of Harmatta involved in the above Interference; that said certified copy was not received by said firm until the 3rd day of August, 1910; that immediately upon receipt of said copy deponent examined into it and found that it was not complete in that prints of two sheets of drawings filed in the case and subsequently cancelled were not included in the copy; that therefore on that day, namely August 3rd, said firm returned the copy to the Commissioner of Patents together with a letter calling attention to the incompleteness of the copy and requesting that the two additional prints be added; that said corrected certified copy was not received to the best of deponent's knowledge and belief by the said firm until late in the day on the 11th day of August, it having been mailed by the Patent Office on the 10th day of August; that at that time deponent, who has had this case in charge, was engrossed in a number of important cases demanding immediate attention and which could not be postponed; that said cases necessitated deponent making two sepa-

rate out of town trips; that at the earliest moment thereafter deponent took up the thorough examination of the Harmatta file wrapper; that the said file wrapper is somewhat lengthy and consumed considerable time in thoroughly digesting it; that the file wrapper appears to be much confused and considerable time was consumed in trying to reconcile the line numbers of the various substitute specifications with the line numbers designated in various amendments as lines to be amended; that besides other numerous amendments three complete substitute specifications and claims were filed which necessarily consumed considerable time in consideration; that the substance of the present motion was practically decided upon the latter part of the month of August, but owing to the intervening holidays and the great press of business in deponent's office taking testimony it was not possible to get the motion papers in proper shape for service until the present time; that no testimony has been taken in the above interference; that no other motions to deponent's best knowledge and belief have been brought in this interference and that the motion is made in good faith and not for purposes of delay.

CHAS. F. TISCHNER, JR.

Sworn to and subscribed before me this 7th day of September, 1910.

MOTION TO DISSOLVE.

Now comes ADOLPH F. RIETZEL, a party to the above entitled Interference, by his attorneys and moves that the Interference be dissolved on the following grounds:

FIRST, that the party Harmatta has no right to make the claims forming the subject of the Interference for the reason that he disclaimed the subject-matter of the counts of the Interference in his substitute specification filed May 14, 1904, beginning with the

paragraph "As Fig. 1 shows" on page 2 and again repeated the disclaimer by his amendment to said specification filed May 18, 1906, and he did not withdraw said disclaimer by merely complying with the Examiner's requirement when he insisted on said requirement that "the description should be confined to applicant's process of welding and not to a discussion of prior processes and their disadvantages."

SECOND, that the party Harmatta has no right to make the claims forming the subject of the Interference for the reason that there is no patentable different between carrying out any process of welding by applying pressure before and during the period of supplying the electric current and by applying pressure only at the moment of the electric current supply as stated at lines 4-10 on page 1 of Harmatta's original specification and the applicant Harmatta by his amendments eliminating the method consisting in applying pressure only at the moment of current supply has disclaimed that method as his invention and therefore has no right to make any claim founded upon the use of pressure and current.

THIRD, that the party Harmatta has no right to make the claims forming the subject of counts 4, 5, 6, 7 and 8 of the issue of this Interference for the reason that he has not filed the oath required by Rule 48 and the Patent Statutes.

BEFORE THE EXAMINER OF INTERFERENCES.

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

No. 31,792.

NOW COMES Johann Harmatta by his attorneys, and in answer to the motions to transmit and the motion to dissolve the above entitled interference brought by the party Rietzel, states, that the passage referred to as a disclaimer is in no sense a disclaimer of the subject matter of the claims in interference, but as will be seen said passage is simply a statement of the effect of the process of welding

thick or heavy sheets where no pressure is applied to the sheets at the welding point during the welding process. To clearly show that such statement is not a disclaimer attention is directed to last paragraph, page 3 et seq., of the amended specification filed May 14th 1904.

The claims 4, 5, 6, 7 and 8 which it is contended cannot be made by the party Harmatta unless accompanied by a supplemental oath are restricted or limited claims and the subject matter thereof embraces a natural consequential condition which must necessarily obtain when the weld is effected as recited in claim 1.

It would be impossible to weld metal sheets by point or spot welding intermittently or at spots only, as for instance as described in the brief description of original Fig. 1 commencing on last line of page 2 of the original specification unless the resulting welded plates had meeting surfaces separated from one another by distinct unwelded areas, and the welded spots "surrounded by distinct areas of unwelded union." These claims therefore simply recite a structure necessarily resulting from a welding as recited in claim 1, and therefore are not such claims as would fall under Rule 48, and therefore it clearly follows that applicant is entitled to make these claims.

In reply to the contention that the party Harmatta has disclaimed the method by eliminating from his specification the method consisting in applying pressure only at the moment of current supply and therefore has no right to make any claim founded upon the use of pressure and current, is not well taken as this is the gist of Harmatta's invention. When an applicant recites two or more alternatives, all of which are mechanical equivalents, he may cancel one or more of the alternatives from the specification and retain one if he chose without in any way disclaiming the other alternatives, providing of course that they are mechanical equivalents. This was clearly held in the case of Hunt Brothers Fruit Packing Company vs. Cassidy, U. S. Circuit Court of appeals, 62 O. G. 1965. In this case it was held that:

> "In Letters Patent #172,608, issued Jan. 25th 1876 to John W. Cassidy for an Improvement in Fruit Driers, the patentee first claimed 'spring or other catches,' but on an objection that his application was not in proper form, amended by striking out 'or other.' Held that this was not a disclaimer of gravity catches, which were known mechanical equivalents of spring catches."

This decision is in accordance with the practice of the Office and does not seem to be open to attack, and applicant in the specification may or may not set forth a number of alternative mechanical equivalents, but should he set forth two or more alternatives which are mechanical equivalents he may cancel one or all of the alternatives and retain one providing they are mechanical equivalents, and

such cancellation from a specification is not a disclaimer of the matter cancelled or of the alternatives cancelled as was clearly held in the above cited case of the Hunt Brothers Fruit Packing Company vs. Cassidy.

It is therefore respectfully submitted that the grounds for transmitting and dissolving the interference are not well taken and that the motions should be dismissed.

Respectfully,

JOHANN HARMATTA,

BEFORE THE EXAMINER OF INTERFERENCES.

IN RE INTERFERENCE No. 31,792.

RIETZEL

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

E. B. MOORE,
6—1652 *Commissioner of Patents.*

This is a motion by Reitzel to transmit to the Primary Examiner a motion to dissolve.

The motion to transmit is opposed, but the opposition relates rather to the merit of the motion than to its transmission.

The motion to dissolve comes after the time allowed by the rules therefor, but the excuse for the delay is clearly sufficient.

The motion to dissolve alleges; (1) that Harmatta has no right to make the claims of the issue become of an alleged disclaimer in

his specification; (2) that Harmatta has no right to make the claims of the issue for certain other reasons specifically set forth; and (3) that said party has no right to make the claims because of the absence of the supplemental oath required by Rule 48.

It is believed that the questions raised under Sections (1) and (2) are such as should be passed upon by the Primary Examiner. The question raised under heading (3) however forms no proper basis for dissolving the interference. It has been repeatedly held that the question of the sufficiency of the oath, either the original oath or a supplemental oath, is an *ex* parte matter which may be readily adjusted after the interference shall have been determined. The motion, therefore, can not be transmitted as to this ground.

The motion to transmit is granted as to grounds (1) and (2). The motion to transmit is denied as to ground (3).

Limit of appeal: September 27, 1910.

The taking of testimony is suspended.

INTERFERENCE No. 31,792.

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

APPEAL TO THE COMMISSIONER.

The party Rietzel to the above interference hereby appeals to the Commissioner of Patents in person from that part of the decision of the Examiner of Interferences rendered September 17th, 1910, refusing to transmit to the Primary Examiner the third ground of the motion to dissolve brought by Rietzel.

The following are assigned as the reasons of appeal:

It was error to refuse to transmit the third ground of the motion to dissolve for the following reasons:

(a) That the question raised is not as to the sufficiency of an oath on file.

(b) That the question as to whether the party Harmatta to the above entitled interference can or cannot make the oath required by the Rules and the Statutes should be settled before the interference is proceeded with.

(c) That the question whether the party Harmatta can or cannot make the oath should be settled before the interference is determined for the reason that if the party Harmatta cannot make the oath required there will be no need to proceed with the contest in reference to the claims involved in the said third ground of the motion to dissolve.

(d) That the question raised by said ground goes to the basic right of the party Harmatta to make the claims involved in some of the counts of the interference and as such should be decided by the Primary Examiner.

ADOLPH F. RIETZEL,

vs.

JOHANN HARMATTA.

INTERFERENCE No. 31,792.

BEFORE THE COMMISSIONER OF PATENTS ON APPEAL FROM THE DECISION OF THE EXAMINER OF INTERFERENCES.

BRIEF FOR RIETZEL.

This case comes up on appeal by the party Reitzel from that part of the decision of the Examiner of Interferences dated September

17th, 1910, refusing to transmit to the Primary Examiner the third ground of the motion to dissolve brought by Rietzel.

The part of the original motion to dissolve referred to is as follows:

"Third. That the party Harmatta has no right to make the claims forming the subject of counts 4, 5, 6, 7 and 8 of the issue of this interference for the reason that he has not filed the oath required by Rule 48 and the Patent Statutes."

The Examiner holds that the question raised under this head forms no proper basis for dissolving the interference for the reason that "it has been repeatedly held that the question of the sufficiency of the oath, either the original oath or a supplemental oath, is an ex parte matter which may be readily adjusted after the interference shall have been determined."

The question raised by Rietzel in this section of the motion is not as to the sufficiency of an oath on file nor to whether the subject-matter of the counts in question is broader than the claims originally filed but goes to the basic right of the party Harmatta to make any such claims as are involved in the counts of the interference in question, which counts are for a subject-matter not claimed originally nor claimed by Harmatta at all until inserted for interference purposes. Harmatta has not filed any oath whatever with respect to the subject-matter of the counts above referred to, the counts being drawn to metal articles, sheets or plates secured together in a certain manner, and the question is therefore not as to the sufficiency of an oath on file but rather as to whether Harmatta can in reality make a proper oath as being the inventor of such articles. And to delay the determination of this question until after the determination of the question of priority in the interference amounts to stating that the Patent Office will try a moot case, which proceeding it has been repeatedly held in the Patent Office will not be followed.

The party Reitzel is a patentee, to whom the claims forming the subject-matter of this interference were granted, and the party Harmatta, a subject of the King of Hungary, is an applicant, who, although his case was on file at the time Rietzel's application was pending, never made any claims to an article of any nature whatsoever until after Rietzel's patent issued when, at the suggestion of the Primary Examiner, he copied the claims from Rietzel's patent and entered into contest as to the counts above referred to. Thus, although his application had been on file for over six years, he had never contended that the article now claimed was in any way his invention and when he found claims were granted to another on subject-matter he never contended was his invention he merely copied the claims and inserted them in his application without complying with the requirements of the Statutes as to the filing of an oath and there is nothing to determine whether he could legitimately make such oath and without first determining such question it cannot be conceived how the Patent Office can sanction any

proceeding allowing him to enter into the contest until it is determined whether he can make a proper oath.

The Statute requires the inventor to make oath that he is the original and *first* inventor. There is grave doubt, as will appear from an inspection of Harmatta's file wrapper, whether he can make such a statement under oath. To delay the determination of this question until after the question of priority has been fought out would be to subject the party Rietzel, against whose patent time is running, to great expense, and why the party Rietzel should be compelled to undergo this hardship until it has been determined whether or not Harmatta has any right whatever to contest priority of these claims cannot be conceived.

The Patent Office is assuming, in withholding the requirement of proper oath before proceeding with the interference, that Harmatta could make such proper oath and therefore the contest as to priority should proceed, but there is nothing in the record to indicate that such a state of facts exists but rather it is evident that the reverse condition is present. That the Patent Office takes the view that in general an interference will not be dissolved or suspended where a supplemental or proper oath has not been filed and sets down this doctrine against all cases irrespective of the merits or points of distinction or differences raised and in fact without even considering them and holds to the hard and fast rule without consideration of the merits or the hardships which might be worked thereby or the injustice which might result, certainly seems, to say the least, to be at variance with the orderly practice that all questions respecting the merits should be definitely decided before proceeding with the contest of priority.

Suppose the interference was proceeded with and it was eventually found that Harmatta could not rightfully make all allegations required in the oath, how would the Patent Office justify itself for not having considered this point before allowing Harmatta to contest these claims?

The subject matter of the claims which were originally sworn to by Harmatta as indicating what was properly his invention was a specific method of electric welding limited in scope and a specific apparatus and not metal plates joined at spots in a certain way by *any* electric welding method adapted for the purpose as called for in the claims forming the subject-matter of counts 4, 5, 6, 7 and 8 of this interference.

Although Harmatta describes the result attained by the practice of one form of his invention as being a joining of plates at spots to take the place of rivets, he did not claim this broad result but only claimed a specific method and a particular form of apparatus for carrying out the method as his invention, by the practice or use of which articles according to the above claims in a restricted sense might be obtained, but which could also be attained by other methods not the invention of Harmatta, thus leading to the inference that he did not make this invention broadly and could not

claim it as being his invention but rather he invented a specific method, claimed to be new, for making certain kinds of articles. This view is strengthened by his specific claims to his preferred form of apparatus, in which he claims "rollers," which rollers make a continuous seam weld. This view is still further strengthened by his statement in his substitute specification filed May 14, 1904, as amended May 18, 1906, to wit: "In known processes the electrodes lie opposite each other, the sheets to be welded by the ordinary process being located between them." Any such process as he herein describes as being old in his knowledge, and therefore disclaims, would result in the metal articles specified in the counts 4, 5, 6, 7 and 8 and therefore he admits he cannot make such claims, the subject-matter being, to his knowledge, old. What knowledge he may have had in mind as a basis for this statement is immaterial to the question in issue. Having made this admission that he cannot claim such articles as his invention, he then seeks to entirely wipe out such admission by merely filing unsupported claims without making oath to the various allegations required by the Statutes before he can even be assumed to be regarded as entitled to make them.

The claims in question are so far at variance with the claims originally sworn to that Harmatta should not be permitted to retain them in the Patent Office for the purposes of interference or for other purposes until it is seen whether he can make a proper oath.

The original specification only sets forth that Harmatta claims to be the inventor of a process and an apparatus and his oath was only made on that specification. Under this oath, Harmatta did not claim any article welded together at a spot or spots but merely claimed a *specific* process. Harmatta may in a brief statement, describe the subject of the claims in a narrow or restricted degree but he has never sworn to a proper oath or an oath of any kind with respect to such claims. The subject of such claims might have been disclosed in some patent or application of his filed more than twelve months before filing his application here or Harmatta might have known he was not the first inventor of *articles* according to said claims or he might have been or is aware that such *articles* were known before his invention or he might not have been at that time or now able to make other allegations required by the Statutes so that he cannot make the necessary oath without perjuring himself, he claiming at that time but a specific process and specific apparatus as his invention and not an article which is not limited to being made by such fanciful process and which might be attained by apparatus other than the specific apparatus claimed by him as his invention.

An examination of the authorities which hold that a motion to dissolve should not be transmitted when based on the requirement of a supplemental oath or the sufficiency of an oath reveal that the question was in those cases occasioned merely by an applicant broadening his claims for interference purposes or where the

question as to the sufficiency of the oath was raised. It is submitted that in this case an entirely different question is in issue—here, the applicant filed claims entirely different as to subject-matter from those originally sworn to and no oath whatever for such subject-matter has ever been made by the applicant.

To go back to the original case holding that a motion of a slightly similar nature to that under discussion should not be transmitted, namely, Rennyson vs. Merritt, 58 O. G. 1415, it was held:

"The question of whether a supplemental oath shall or shall not be requirerd is ex parte in its nature and not open to argument on the part of an opposing interference contestant."

In this case the question arose by one applicant filing broader claims than those originally sworn to but of the same nature. The case is entirely different from the one presented in this interference and to hold that the case just cited is a pertinent authority for following its holding in the present case amounts to saying that insofar as the party Rietzel is concerned it does not matter whether Harmatta can properly make the claims or not; Rietzel cannot argue the question and he must contest priority even though in the end it is found that Harmatta was not properly entitled to make the claims.

This quesion as to whether Harmatta can make proper allegations under oath is a mighty vital point to the interference owing that he has never established his right to them as required by Statute and it is in this point that the present case differs from all previously decided cases. If Rietzel is not interested in this point and cannot be heard in argument as to why Harmatta should be compelled in this case to file a proper oath it cannot be seen what rights he has got in the interference.

If Harmatta cannot make the necessary oath why should he have the right to contest priority and he should not be allowed to contest priority until it is seen whether he can make the oath and properly assert his rights to the claims in conformity with the requirements of the Statutes.

If the interference is not dissolved with respect to the counts referred to on account of the lack of this oath it should, in justice, be suspended pending the filing or non-filing of such an oath and the party Rietzel should certainly be allowed to argue the merits of his contention regarding the necessity of settling the question of Harmatta's rights in this interference before the proper tribunal, the Primary Examiner, following all requirements of orderly procedure, and to hold, that merely because in previous cases a somewhat similar motion was not transmitted and was lacking in merit, that Rietzel's motion is lacking in merit without even considering the merits that can be advanced in its favor is entirely contrary to a proper and lawful recognition of Rietzel's rights in this interference.

In conclusion, we would say that rather than adhere to the broad proposition, that in no case will a motion to dissolve be transmitted

which is based on the lack of or the sufficiency of an atth irrespective of the merits or the points which demand the filing of such proper oath as vitally affecting the right on one party to enter into the interference, the exigencies of the particular case at issue should be carefully weighed and passed upon. As the practice stands now on this point, a broad rule is followed hard and fast and the justice or injustice will not be considered. It is respectfully submitted that in this case there are ample and sufficient reasons, as set forth above, for departing from such hard and fast holding and for transmitting the part of the motion to dissolve in question to the Primary Examiner for decision and it is respectfully requested that the Commissioner transmit such question for thorough consideration and careful determination by the Primary Examiner.

Respectfully submitted,
TOWNSEND & DECKER,
C. F. TISCHNER, JR.,
Attorneys for Rietzel.

SET

IN THE UNITED STATES PATENT OFFICE.

RIETZEL

vs.

HARMATTA.

PATENT INTERFERENCE No. 31,792.

APPEAL ON MOTION.

ELECTRIC WELDING.

Patent granted Adolph Rietzel July 20, 1909, No. 928,701, on Application filed February 24, 1905.
Application of Johann Harmatta filed December 3, 1903, No. 183,677.

Messrs. Townsend & Decker for Rietzel.
Messrs. O. E. Duffy & Son for Harmatta.

This is an appeal by Rietzel from that portion of the decision of the examiner of interferences refusing to transmit to the pri-

mary examiner the third ground of his motion to dissolve the interference.

This ground reads as follows:

> "Third, that the party Harmatta has no right to make the claims forming the subject of counts 4, 5, 6, 7 and 8 of the issue of this interference for the reason that he has not filed the oath required by Rule 48 and the Patent Statutes."

Transmission of this part of the motion to dissolve was denied by the examiner of interferences upon the ground that the sufficiency of the oath is an *ex parte* matter which may be readily adjusted after the interference shall have been determined.

The record shows that the application of Harmatta as filed disclosed a method, an apparatus, and an article, but contained only claims to the method and apparatus. The examiner suggested to him, under the provisions of Rule 96, both method and article claims from the patent to appellant, which had in the meantime inadvertently issued upon a subsequently filed application. The amendment of Harmatta insèrting his claims was not accompanied by a supplemental oath.

It is well settled that the question of whether claims inserted by amendment should be supported by a supplemental oath is an *ex parte* matter not open for argument in the interference proceeding, and that in the absence of such an oath, even where it should have been furnished, there is no such irregularity as will preclude the proper determination of the interference. Rennyson v. Merritt, 58 O. G., 1415; Kane v. Brill and Adams, 84 O. G., 1142; *ex parte* Richards, 95 O. G., 1853; Silverman v. Hendrickson, 99 O. G., 445; Auerbach v. Gubing v. Wiswell, 108 O. G., 289; Schubert v. Munro, 113 O. G., 283; Phillips v. Sensenich, 134 O. G., 1806, 31 App. D. C., 159.

It is urged by appellant that he should not be put to the expense of contesting the interference where there is doubt as to whether his opponent "can make such a statement under oath." In answer to this contention it is noted that the issue in the interference includes both method and article claims, and the interference would continue as to the former claims, even if this ground of the motion to dissolve were granted, also that Harmatta has filed a preliminary statement in which he alleges that he is the inventor of the issue in the interference. In the latter respect this case is similar to that of Silverman v. Hendrickson, *supra*.

Appellant suggests that the interference should be suspended, at least, and Harmatta required to file a supplemental oath.

In the case of Rowe v. Brinkmann, 133 O. G., 515, where the original oath of Brinkmann was defective, a motion of Rowe to dissolve the interference based upon this ground was refused transmission but it was directed by the Commissioner upon appeal that the interference be suspended and a proper oath required

for the reason that "Brinkmann had filed no preliminary statement." In the present case, as stated above, Harmatta has filed a proper preliminary statement.

The decision of the examiner of interferences is affirmed.

E. B. MOORE,
Commissioner.

INTERFERENCE No. 31,792.

ADOLPH F. RIETZEL.

vs.

JOHANN HARMATTA.

ON APPEAL TO THE COMMISSIONER OF PATENTS.

NOW COMES ADOLPH F. RIETZEL by his attorneys and moves for a rehearing of his appeal decided by the Commissioner of Patents December 3rd, 1910, upon the following grounds:

I.

The Commissioner arrived at his conclusion through overlooking the controlling effect of the fact that in making his original application for patent Harmatta swore only that he believed himself to be the original, first and sole inventor of a process of and apparatus for manufacturing metal articles, and did not swear that he believed himself to be the first and sole inventor of the metal article itself, and has never filed any oath or made any affidavit that could be lawfully taken as a substitute for a formal oath, that he believes himself to be the first and original inventor of the article forming the subject of the fourth, fifth, sixth, seventh and eighth issues of the interference.

II.

The decision of the Commissioner was in direct conflict with Section 4892 of the revised Statutes requiring that an applicant making application for a patent upon a manufacture or improvement thereof shall make oath that he believes himself to be the first inventor thereof and does not know and does not believe that the same was ever before known or used, and the applicant Harmatta has never filed any oath to that effect in this case or any lawful substitute therefor.

III.

The decision of the Commissioner was reached through misapprehension as to the controlling effect of the previous decision in Silberman vs. Hendrickson, 99 O. G., 445, and of the fact that Harmatta has filed a preliminary statement. It was not thereby decided that a preliminary statement can supply the place of the oath required by Section 4892 of the Statutes as to all the statutory allegations, but only that a preliminary statement in which the inventor makes oath that he is the inventor of the matter in issue may stand in place of the application oath as to that fact.

IV.

The Commissioner arrived at his conclusion through misapprehension as to the controlling effect of said preliminary statement through overlooking the fact that said preliminary statement does not allege that the inventor believes himself to be the first inventor or discoverer of the manufacture or improvement of manufacture claimed in the fourth, fifth, sixth, seventh and eighth counts of the issue.

V.

The Commissioner arrived at an erroneous conclusion through failure to distinguish between the previously adjudicated cases, decided upon the case of a broadened or enlarged claim upon the

same statutory subject matter of invention sworn to by the original oath, and the case of a new claim upon different statutory subject matter to which no oath of any kind has been made.

VI.

The decision was in principle in direct conflict with Section 4904 of the Statutes, prescribing in what cases the Commissioner shall direct the Primary Examiner to proceed to determine the question of priority of invention and for the reason that Harmatta has not filed any complete application for patent for the article forming the subject of the counts 4, 5, 6, 7 and 8, conformably with Section 4892 of the Statutes and Section 46 of the Rules of Practice, specifying the facts to which the applicant shall make oath, and has not filed any complete application conforming to Section 30 of the Rules of Practice and to the Statutes.

VII.

The decision overlooked the controlling effect of the fact that the oath required to be filed by Harmatta in order to complete his application for a patent on the article forming the subject of counts 4, 5, 6, 7 and 8 of the issue is in law an original oath and that in the absence of such oath the declaration or continuance of an interference by the Commissioner is ultra vires and in conflict with Section 4904 of the Statutes, prescribing the cases in which the Commissioner shall proceed to determine the question of priority of invention.

VIII.

The decision overlooked the controlling effect of the fact that no oath has been at any time filed by Harmatta that he believes himself to be the first inventor of the article of manufacture forming the subject of the counts 4, 5, 6, 7 and 8, but that on the contrary he has in his original specification inferentially disclaimed being the first inventor of the article, for producing which he invented the apparatus and method for which he duly made application for patent.

IX.

In arriving at his conclusion the Commissioner overlooked the fact that the authorities cited by him in his decision do not warrant the declaration of an interference or the continuance of the same in cases where there is an entire absence of oath.

X.

The Commissioner arrived at his conclusion through misapprehension of the controlling effect of the decision in the case of Rennyson vs. Merritt, which was a case in which the applicant simply broadened his claims, confining them still to the statutory subject matter covered by his original oath.

XI.

The Commissioner arrived at his conclusion through misapprehension as to the controlling effect of the previous decision in the case of Kane vs. Brill & Adams, which dealt only with the case of a supplemental oath where the inventor had been required by the Examiner to amend his specification to make his device operative.

XII.

The Commissioner arrived at his conclusion through misapprehension of the controlling effect of the decision in the case of Ex parte Richards, which decided only that the requirement of a supplemental oath where claims were broadened would be postponed until after the interference, in view of hostility of the inventor to the assignee at the time.

XIII.

The decision was reached through misapprehension as to the controlling effect of the case of Auerbach vs. Gubing vs. Wiswell, 108 O. G. 289, for the reason that said decision was made upon the authority of Rennyson vs. Merritt and Kane vs. Brill & Adams, and like them, dealt with the case of an enlarged but not a different claim.

XIV.

The Commissioner reached his conclusion through misapprehension of the controlling effect of the decision in the case of Shubert vs. Monroe, 113 O. G. 283, which was not rendered upon any state of facts differing from the previous cases of Rennyson vs. Merritt and others cited with approval, and which was rendered upon a state of facts entirely different from those present in this case. The facts in Shubert vs. Monroe, so far as said decision shows on its face, differed only from the previous cases in that there was an absence of a notarial seal upon the supplemental oath. This case, like the others, was an appeal from the Primary Examiner after decision upon the question referred to him by the motion made in view of the absence of a supplemental oath. It was not therein decided that the question raised should not be referred to the Primary Examiner for his consideration.

XV.

The conclusion of the Commissioner was reached through misapprehension as to the controlling effect of the case of Phillips vs. Sensenich, in which the court simply refuses to undertake to review the exercise of discretion by the Commissioner in regulating the practice of the Patent Office as to supplemental oaths. It appears further from the decision that the amendment in question was "within the scope of the original application" and involved merely

In the matter of the Interference of

RIETZEL

vs.

HARMATTA.

INTERFERENCE No. 31,792.

REQUEST FOR REHEARING.

You are hereby informed that the decision of the Commissioner on the above request is as follows:

"This is a request by Rietzel for a rehearing of his appeal from that portion of the decision of the examiner of interferences refusing to transmit the third ground of his motion to dissolve the interference.

"It is well settled that the question of whether a supplemental oath should be required is an ex parte matter upon which the proper determination of priority is not dependent. In the preliminary statement of Harmatta, he alleged 'that he conceived the invention set forth in the declaration of interferences at the end of the year 1900.' This preliminary statement is believed to be sufficient for the continuation of the interference and the question of whether a supplemental oath should be filed will be determined by the primary examiner after the interference is concluded.

"The petition for rehearing is denied."

BEFORE THE EXAMINER OF INTERFERENCES.

IN RE INTERFERENCE NO. 31,792.

RIETZEL

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

E. B. MOORE,
Commissioner of Patents.

On January 7, 1911, Harmatta filed a motion to amend the issue of this interference by adding certain claims. The motion is not accompanied by a motion to transmit to the Primary Examiner but its transmission will be considered in order to save the moving party the inconvenience of bringing another motion therefor.

It appears that the Primary Examiner has jurisdiction of this case for the purpose of deciding a motion for dissolution upon which no hearing has as yet been had. It is considered, therefore, that the present motion, although late, should be transmitted to the Primary Examiner since it can be considered with the questions which he is already called upon to determine and no substantial extra delay will result in the prosecution of this interference.

Harmatta's motion to amend is transmitted to the Primary Examiner.

Proceeding stand suspended.

H. E. STAUFFER,
Examiner of Interferences.

Docket Clerk.

31,792—35

WASHINGTON, D. C.,

January 14, 1911.

Hon. Commissioner of Patents,
Washington, D. C.

SIR:

In the matter of the Interference Rietzel vs. Harmatta, No. 31,792; in which Rietzel is a patentee and Harmatta an applicant.

In inspecting the file of this case we have seen a letter from the Primary Examiner requesting jurisdiction of the case to consider the counts of the interference in view of alleged newly discovered references.

We desire to call attention to the fact that the Rietzel Patent in this interference is now involved in infringement suits and that the question of patentability has been raised therein and will be considered more exhaustively, completely and finally that could be done by the tribunals of the Patent Office. For this reason we request that the Primary Examiner be directed not to consider such question of patentability at the present time, it being understood that should Harmatta prevail it could be urged at any time before the issuance of the patent while if Rietzel should succeed, the consideration of patentability would be a moot question, since he already has a patent.

Attention is also called to the fact that Harmatta could not raise the question of patentability since his opponent has a patent and if he raised it, the interference would, under the practice, be dissolved.

Very respectfully,

TOWNSEND & DECKER.

In view of the facts above stated it seems to me that the above request could well be granted without impairing the rights of either party, as far as the interference is concerned.

Very respectfully,

WM. J. RICH,
Examiner Division 3.

UNITED STATES PATENT OFFICE.

In re Interference:

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

No. 31,792.

APPEAL TO THE COMMISSIONER OF PATENTS.

The party Rietzel to the above interference hereby appeals to the Commissioner of Patents in person from the decision of the Examiner of Interferences rendered January 14, 1911, transmitting to the Primary Examiner the motion filed by Harmatta to amend the issue of the interference by adding certain claims.

The following are assigned as the reasons of appeal:

It was error to transmit to the Primary Examiner Harmatta's motion to amend for the following reasons:

(a) That the motion was not brought within the time allowed by the Rule for bringing such motions.

(b) That the motion was brought outside of the time allowed by the Rule and no sufficient showing was made why the motion could not have been brought earlier.

(c) That the transmission of the motion was opposed by the party Reitzel, which face does not appear from the said decision of the Examiner of Interferences.

It was error to hold that the motion should be transmitted because a motion to dissolve in this same case is awaiting hearing, for the reason that this is not a sufficient or recognized excuse for bringing a motion after the time allowed by the Rule.

It was error to hold that because the Primary Examiner has jurisdiction of the case for the purpose of deciding another motion that he should be given jurisdiction to decide this motion, which is brought far outside of the time allowed by the Rule.

UNITED STATES PATENT OFFICE,

In re Interference:

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

No. 31,792.

BEFORE THE HONORABLE COMMISSIONER OF PATENTS ON APPEAL FROM THE EXAMINER OF INTERFERENCES' DECISION TRANSMITTING HARMATTA'S MOTION TO AMEND.

BRIEF FOR ADOLPH F. RIETZEL.

THIS CASE comes up on appeal by the party RIETZEL to the above entitled Interference from a decision of the Examiner of Interferences rendered January 14th, 1911, transmitting the motion to amend the issue of the Interference brought by Harmatta.

The Interference is between Adolph F. Rietzel, a patentee, and Johann Harmatta, who has filed an application in which certain claims of the Rietzel patent are incorporated.

On January 7th, 1911, over six months after the preliminary statements in the above Interference were approved, the party HARMATTA filed a motion to amend the issue of this Interfer-

ence by adding certain additional claims which he copies from the patent issued to Rietzel. This motion is not accompanied by any excuse or showing to explain the delay in bringing the motion other than that the attorneys for Harmatta "did not receive instructions from their client, Mr. Harmatta, in order to bring this motion within the time specified by Rule 109". They do not state when they did receive their instructions, why they themselves could not have brought the motion, why they could not have brought the motion at an earlier date, nor in fact any reason whatever to in any way explain their lack of diligence in presenting the motion.

The party HARMATTA has had constructive notice of the Rietzel patent for about a year and a half and he deliberately copied certain claims of this Rietzel patent for the purpose of Interference. The Rietzel patent was issued some nine months before the declaration of interference and the party HARMATTA assuredly knew of all the claims in the Rietzel patent when he deliberately copied but some of them and he now attempts, after a lapse of over six months from the time of approval of the preliminary statements, to come in and add certain other claims of the existence of which he was aware at the time of making the original claims. Further, he makes this motion far outside of the time allowed by the Rule and without attempting to make any showing whatever to excuse the delay.

Rule 109 requires that a motion to amend shall be presented within thirty days after the preliminary statements of the parties have been approved and as regards this time requirement would seem to be more mandatory than the Rule 122, which states that motions for dissolution should, *if possible,* be made not later than the thirtieth day after the statements of the parties have been approved. The purpose of Rule 109 is to permit a party to an interference to add additional claims from an opponent's case after he has had an opportunity to inspect his opponent's case, and as was held in Sutton, Steele & Steele, 121 O. G. 1012, if he fails to take advantage of that Rule he looses the right to contest the question of priority as to the additional claims made by his opponent.

Harmatta had ample time before the thirty day period allowed by the Rule expired, to include all counts in the Interference which he thought he could make, and in fact all such counts should have been included when he originally copied some of the claims of the Rietzel patent, as at that time he had access to the patent and knew of all the claims made therein. As he made his election, having full knowledge of all the claims in the patent, he has now waived his right to contest any additional claims and his present motion brought far outside of the time allowed by the Rule, should not be transmitted, as was held in the case of Scott vs. Emmet vs. Hewett, 116 O. G. 1184.

This matter, it is contended, comes well within a decision rendered by the present Commissioner of Patents, Mr. Moore, in Mattice vs. Langworthy, 132 O. G. 678, in which it was held:

> "A motion to amend under Rule 109 brought after the thirty days allowed by the Rule and accompanied by no excuse for the delay is entitled to no consideration and should not be transmitted."

Also in Potter vs. Van Vleck vs. Thomson, 95 O. G. 2484, it was held:

> "In order to warrant transmitting a motion filed after the twenty days allowed by the Rule, it must be satisfactorily explained why it was not possible to bring it within the time. The fact that the reasons for it did not occur to the party bringing it when the information was within his reach is not a sufficient excuse."

Harmatta could have brought the present motion within the time allowed by the Rules just as well as he can bring it now, over five months after the time has expired, and in fact if he had any contention that he could make the claims set forth in the present motion, he should have made them when copying his original claims from the Rietzel patent, as the Rietzel patent was under his notice at that time and he had full knowledge of all the claims of the patent.

This case, that is where a party deliberately copies claims of a patent to provoke an interference, is entirely different from one in which two applicants are involved in which latter case neither one knows of the claims involved in the application of the other until after the preliminary statements are approved and each can obtain copies of his opponent's application.

It is now nearly twelve months since the time that the Rietzel patent was specifically brought to Harmatta's attention and he had ample time between the time of calling the patent to his attention and the time he copied his first claims to decide just what claims he could contest in the Interference and in view of this long time within which the information was at his hand his present motion to add additional claims not originally copied from the Rietzel patent should not be transmitted in view of the lateness with which the motion is brought and the absence and impossibility of any valid excuse for the delay.

It is contended that the Examiner of Interferences has gravely abused his discretion in transmitting the motion in view of the facts and without any excuse being given for the delay. The Examiner of Interferences evidently takes the view that because there is a motion to dissolve pending, that this is sufficient to excuse the delay in presenting the present motion to amend. This has been repeatedly held to be an insufficient excuse as is evidenced by numerous decisions on this point, among which may be noted the following:

Perrussel vs. Wichmann, 99 O. G. 2970, in which it was held:

"The fact that a motion to dissolved under Rule 122 is pending does not prevent the filing of a motion to amend under Rule 109 or excuse delay in filing such a motion."

Hall vs. Latta, 59 O. G. 1431, in which it was held:

"The pendency of other motions in an Interference is no excuse for delaying a motion to dissolve the Interference beyond the twenty days limited by the Rule."

It has been repeatedly held that the Examiner of Interferences should only consider whether the motion is brought within the time allowed by the Rule and is in proper form and it cannot be see how the Examiner can abrogate such holdings and the strict requirements of the Rule where there has been absolutely no showing made to warrant dispensing with the strict requirements of the Rule.

The practice as regards Transmission under Rule 109 closely follows that under Rule 122 except it is contended that the time limit in Rule 122 is more lenient than that specified in Rule 109 and therefore the showing to excuse delay under Rule 109 should be more thorough and convincing than that necessary under Rule 122. If the Examiner of Interferences' decision in this case transmitting Harmatta's motion to amend, brought late and unexcused, merely because the motion to dissolve is pending, is tenable, then it amounts to establishing, as a Rule of Practice, that

A party in an interference proceeding, provided there is a motion to dissolve pending, can bring any other motions allowed by the Rules at any time outside of the time limit required by the Rules, provided the motion is brought before the hearing on the motion to dissolve, and in such cases he will not be required to excuse his delay in presenting the second motion.

A fact which does not appear from the Examiner of Interferences' decision is that the transmission of Harmatta's motion to amend was vigorously opposed by Rietzel at the hearing before the Examiner of Interferences on the ground that the motion was brought along after the time allowed by the Rule and no sufficient showing was made to excuse the delay, and for this reason alone, as was held in Townsend vs. Copeland vs. Robinson, 124 O. G. 1845, the transmission should be refused.

In the matter of excusable and inexcusable delay in bringing motions such as the present one, the burden is entirely upon the party who brings the motion to show that he went diligently to work on his case at the proper time to discover whether a motion should be brought and when he does not or cannot make a proper excuse, it is thought that the Examiner of Interferences gravely abuses his discretion when he overlooks the lack of an excuse and transmits the motion. What constitutes excusable and inexcusable delay is further clearly set forth in McKee vs. Baker, 120 O. G. 657, in which it was held:

"Where it is not shown that a party went diligently to work upon his case at the proper time to discover whether a motion for dissolution should be brought nor that he was prevented from making the necessary investigation and bringing the motion within the period fixed by the rules, HELD that the motion should not be transmitted."

"The rule requiring motions to be brought within a fixed time is a wholesome one, and its enforcement requires that motions be not accepted when brought after the expiration of that time except where circumstances are shown which made it impossible to bring the motion within the regular period or under which the party could not reasonably be expected to have brought it therein."

In view of the peculiar and exacting facts presented in this matter, it is respectfully submitted that there has been a clear abuse of discretion on the part of the Examiner of Interferences in transmitting Harmatta's motion to amend and it is respectfully requested that such decision of the Examiner of Interferences be reversed.

ELECTRIC WELDING.

Application of Adolph F. Rietzel filed February 24, 1905, No. 427,081.

Application of Johann Harmatta filed December 3, 1903, No. 183,677.

Messrs. Townsend & Decker for Rietzel.
O. E. Duffy & Son for Harmatta.

This is an appeal from the decision of the examiner of interferences transmitting a motion by Harmatta to amend the issue by adding three claims contained in an amendment accompanying the motion.

The party Rietzel is a patentee and Harmatta an applicant. The

three claims which Harmatta seeks to have added to the issue are copied from the Rietzel patent. Transmission of the motion is opposed on the ground that no excuse has been shown by Harmatta for the delay in bringing this motion. As pointed out by the examiner of interferences, however, the primary examiner now has jurisdiction of the case for the purpose of considering a motion for dissolution and the additional delay incident to a determination of the present motion would be insignificant under the circumstances.

Furthermore, Harmatta should be given every reasonable opportunity for securing in this interference an adjudication on all claims which may be properly made in his application, since Rietzel is a patentee and there will therefore be no opportunity after the termination of the interference for the office to reject any claims in the Rietzel patent which may be unpatentable over the present issue, should Harmatta prevail in this proceeding.

It does not appear that the transmission of the present motion will prejudice any rights of the opposing party.

The decision of the examiner of interferences is affirmed.

BEFORE THE PRIMARY EXAMINER.

In re Interference:

ADOLPH F. RIETZEL.

vs.

JOHANN HARMATTA.

No. 31,792.

BRIEF FOR RIETZEL ON MOTION TO DISSOLVE.

This is a motion by the party Rietzel to dissolve the above interference for the reason that the party Harmatta has no right to make the claims constituting the subject-matter of the interference.

On page 1 of Harmatta's substitute specification, filed May 14, 1904, beginning with line 11, he describes what he says to be the ordinary systems of welding, in which he states that the objects to be welded are placed one on the other, the current passed from one to the other and after they have been brought to a welding heat they are finally pressed together to effect the desired union. On the following page, namely 2, he describes two figures, namely, Fig. 1 and 2, of a set of drawings filed with this substitute specification. The figures referred to are herewith reproduced by a tracing of the same, and marked for identification "A." Harmatta describes these figures on page 2 of his specification, above referred to as follows:

> "Figure 1 is a sectional view illustrating the electric welding of two comparatively thick sheets on the ordinary system.
> "Figure 2 is a like view showing what occurs when one of the sheets is thin."

On line 21 of the same page, he goes on to describe, more in detail, the apparatus shown in these figures in the following words:

> "As Figure 1 shows the electrodes *a b*, lie opposite each other, the sheets 1, 2 to be welded by the ordinary process being located between them. The sheets lie loosely upon each other, that is to say, they are not artificially pressed together, and the consequence is that they are separated by a layer of air 3."

only at the moment of this supply, at the place at which the welding is to be done." He stated in his substitute specification, above referred to, that it was the ordinary process to supply pressure after the supply of current. The Examiner cited a number of references which meet the invention of applying the pressure at the place at which the welding is to be done at the moment of the current supply, among which references may be mentioned the Thomson patent, No. 444,928. Harmatta, then, due to the citation of these references, canceled any claims broad enough to cover the application of pressure only at the time of the current supply and eliminated such method from his invention on account of it also being old in the art.

As Harmatta practically states in the lines above referred to that there is no patentable difference between the application of the pressure before and during the period of supplying the current, and the application of pressure only at the moment of current supply, and in fact there is no patentable difference, Harmatta has no right to make any claim founded upon the use of current and pressure, when, by the Examiner showing it to be old in the art to apply the pressure at the point of welding only at the moment of supplying the electric current, Harmatta canceled and disclaimed this method as his invention, the other equivalent is thereby absolutely met and Harmatta had no right to make any claims founded on such application of pressure and current. As he describes this last specific method as his invention, still less has he any right to make claims broad enough to include the use of an old apparatus and an old process, which he states were old in the art and therefore not his invention.

The specification of Harmatta stood with the disclaimer for nearly six years and not until he filed the amendments on Jan. 27th and March 30th, 1910, did he attempt to correct the specification by removing the disclaimer and broadening his claims. It appears nowhere that the insertion of the disclaimer was through inadvertence, accident or mistake, nor does it appear that the long delay was through any misapprehension of the applicant's rights. It is well settled that the correction of a mistake or error, if it can be made at all, may be lost by delay and particularly where intervening rights would be thereby effected. This cardinal principle of the patent law has been expounded so fully and forcibly in connection with litigated reissue patents that it is so well settled that it is not now necessary to cite authorities.

It is manifest that the correction or amendment of the specification and claims made by Harmatta can only avail him and can only be lawful by relating back to the date of the supposed error in disclaiming as new with him the broad art of welding in spots; but the rule as above stated, here intervenes to bar the proposed change for the reason which the correction which Harmatta now seeks to make affects the intervening rights of Rietzel as conferred upon him by the issuance of his patent.

The proposed correction further operates adversely upon the rights of Rietzel and his assignees as exercised by them for a period of nearly one year after the issuance of the Rietzel patent. Even in the case of the correction of a mere clerical error it has been held that such correction cannot take effect and relate back to the date of the error, if intervening rights would be thereby affected. This is stated to be the law in the foot-note to Sec. 639 of Robinson on Patents, citing *Woodworth vs. Hall*, (1846), 1 W. & M. 389; 2 Robb. 517. This was held to be the rule in the case of a mere clerical error on the part of the Patent Office. The same principle and rule applies with much more force in the case of a correction intended to broaden the scope to affect intervening rights, as has been over and over stated by the courts in its decisions upon reissue patents.

It is a matter of grave moment in determining whether the rights of Rietzel and his assignees are adversely affected at this late date to remember that the Harmatta British patent contains substantially the same disclaimer which he now seeks to wipe out of his United States application, and that the owners of the Rietzel invention have proceeded on their actual knowledge of that disclaimer ever since the Harmatta patent was cited in the course of the prosecution of the Rietzel application eventuating in his patent herein in interference.

We therefore contend that Harmatta is precluded from making the correction which he now seeks to make by reason of delay, by reason of intervening rights which would be adversely affected, by reason of not only the absence of a showing of inadvertence, accidet or mistake in the matter which he now seeks to correct as an error, but on the contrary a presumption (conclusive, not rebuttable) of the absence of inadvertence or mistake and arising from an express and formal declaration made in such terms that it is not possible to assume that any error or mistake actually existed in the making of that declaration.

Moreover, even if a patent should issue to Harmatta, that patent would have to be construed in the light of the disclaimer found in his British Patent, and so construed would obviously be invalid for the claims which he now seeks to make.

It is for the Patent Office to determine, therefore, whether it will continue this interference with a view to determining whether a patent shall be issued to Harmatta under circumstances such that, if the patent should issue, said patent would have to be declared invalid under the express authority of the decision of the United States Supreme Court in the case of *Ashcroft vs. Boston & Lowell Railroad Co.* (1877), 97 U. S. 189. In that case it was expressly held that where the foreign patent of an inventor contains a disclaimer of certain features, the American patent for the same invention must be limited in the same way. This is laid down as a broad and cardinal principle of the Patent Law as is apparent from the text of the decision. The case went up on a number of assignments of error, the first of which was:

"That the court erred in giving weight to the disclaimer of the supposed inventor as set forth in his English patent."

The patentee in this country, it appeared, took his original patents limited practically by the same disclaimer as appeared in the British patent, that is to say, they were comparatively narrow claims. One of them, however, was reissued and on that reissued patent a suit was founded. It appeared, further, that both the original and the reissued patent were granted for the same invention as the English patent. When reissued the patent contained no disclaimer of the kind mentioned in the English patent, though it was conceded that both the original and the reissued patent were granted for the same invention as the English patent.

The same is true in the present case and that concession in this case could not properly be withheld, for Harmatta has set forth in his original oath and by his preliminary statement that the invention for which he now seeks patent is the same as that of his English patent.

In the case decided by the Supreme Court, and now referred to, the court says, speaking of the disclaimer of the English patent and which in its nature was no more explicit than that of Harmatta:

"Explicit as that disclaimer is, still it is assigned for error by the complainant that the Circuit Judge erred in giving weight to it; but the court here is of the opinion that there is no merit in that objection. *Instead of that, the court decides that the patent in suit, in order that it may be held valid, must be construed in view of the disclaimer contained in that patent,* and he limited to the particular devices shown in the specification for effecting such recoil action of the steam."

We strenuously urge on the authority of this case that Harmatta is not entitled to make the claims of this interference.

TOWNSEND & DECKER,
Attorneys for Rietzel.

IN RE INTERFERENCE 31,792.

RIETZEL

vs.

HARMATTA.

A. F. Rietzel,
c/o Townsend & Decker,
149 Broadway, N. Y. City.
Johann Harmatta,
c/o O. E. Duffy & Son,
612 F St., N.W., Washington, D. C.

Please find below a communication from the Examiner in regard to the above-cited case.

Very respectfully,
E. B. MOORE,
Commissioner of Patents.

6—1759

This interference is before the Primary Examiner in view of a motion made by Rietzel to dissolve and a motion made by Harmatta to add new counts under Rule 109.

The grounds of the motion to dissolve are—

(1) That Harmatta has no right to make claims corresponding to the counts of the interference issues inasmuch as he disclaimed the subject-matter thereof in his substitute specification filed May 14, 1904.

(2) That Harmatta has no right to make the claims corresponding to the counts of the interference for the reason that there is no patentable difference between carrying out any process of welding by applying pressure before and during the period of supplying the electric current and by applying pressure only at the moment of the electric current supply and that Harmatta has disclaimed the latter by certain amendments made to his specification.

The two grounds of the motion, as may be seen, are based on alleged disclaimers by Harmatta made in the application file. It is here noted that it appears questionable whether the acts of Har-

matta, alluded to by Rietzel, even if the contention be correct, can properly be termed "disclaimers" but since such word has been used by Rietzel and since the meaning is clear, whatever term may be used, such term will be employed in this decision.

Of the parties to this interference Harmatta filed his application Dec. 3, 1903 and Rietzel Feb. 24, 1905. Rietzel's application was allowed June 24, 1909 and patented July 20, 1909, while Harmatta's case was pending. March 22, 1910, certain claims of Rietzel's patent were suggested to Harmatta for purpose of interference, under Rule 96. Harmatta making such claims, the interference was declared.

The subject-matter of the interference involves what is called "spot" welding, wherein the parts to be joined (thin sheets), are electrically welded at certain spots or places instead of over their entire surface. In Rietzel's process projections are formed on one or both of the juxtaposed surfaces or a metal washer may be placed between such surfaces; metal electrodes are placed over such projections, an electric current is passed through the electrodes and pressure is exerted upon the pieces simultaneously with the passage of the electric current, one of the electrodes being forced against the pieces.

Harmatta's process is substantiaally the same as Rietzel's with this variation: no projections are formed upon the opposing surfaces but such surfaces are pressed together by the electrode as the current passes, thus forming the weld.

Although Rietzel does not disclose any means wherein the welding is accomplished without the presence of projections the claims in interference are of sufficient breadth to cover both his process and that of Harmatta.

Since the motion only alleges matter connected with Harmatta's application, it is unnecessary to refer more specifically to Rittzel's process or apparatus.

Harmatta's original specification contained the following statement of invention (line 7, page 1 to line 17, page 2):

> "My invention relates to a process of and apparatus for manufacturing metal articles of all kinds, in particular those of the thinnest sheet metal, by direct electric welding. The new process consists in one of the electrodes (or both of them) not only serving to feed the current, but also being employed for exercising a more or less strong pressure either before and during the period of supplying the electric current, or at the moment of this supply, at the place where the welding is to be done. The member which feeds the electricity is thus at the same time the tool, and in this manner the most favorable conditions of working possible are secured, since, as is well known, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough.

"According to none of the present known electric welding processes are the articles to be welded firmly pressed together during the welding operation by one or both electrodes for the purpose of favoring welding. Hitherto either no pressure has been extended at all, or it has been exercised at a certain distance from this place of welding, or at all events not centrally direct upon the electrodes pressing on the place to be heated. In short, hitherto direct electric welding pressure has never been exercised by means of the electrodes located in the direction of the current directly above the surface or point being welded."

By amendment of May 14, 1904, the entire specification was canceled and a new specification presented which contains the following: (line 3, page 1 to line 6, page 5).

"As well known, it is impossible, by means of the ordinary methods of electric welding, to produce a really sound seam between very thin metal sheets, that is to say, a seam which is perfect at every part, without there being any fusing or burning away of the material being welded."

The reason of this I have ascertained to be as follows:

"On the ordinary systems of welding it is the practice at once to lead a current to the objects to be welded (such as iron bars, hoops, chain links, or the like), whereby, in consequence of the thinner or thicker layer of air, which is always present between the two objects, vigorous sparking occurs. There is, so to say, a line of sparks or an arc formed, which persists until the objects being welded have been brought to melting heat by the electric current, whereupon they are finally pressed together to effect the desired union.

"This well-known method, therefore, does not really differ from the ordinary method of welding at the fire, except that instead of the gases of combustion of the fuel, the electric current is employed to heat the bodies to be welded. Once the welding heat is reached, however, the final union of the bodies in either case is effected by mechanical pressure (pressing or hammering).

* * * * * * *

"Fig. 1 is a sectional view illustrating the electric welding of two comparatively thick sheets on the ordinary system.

"Fig. 2 is a like view showing what occurs when one of the sheets is thin.

* * * * * * *

"As Fig. 1 shows, the electrodes a b lie opposite each other, the sheets 1, 2 to be welded by the ordinary process being located between them. The sheets lie loosely upon each other, that is to say, they are not artificially pressed together, and the consequence is that they are separated by a layer of air 3.

"If now the electric circuit is completed through the two

electrodes and the sheets, and if the layer of air 3 is sufficiently thick, that is to say, the air resistance sufficiently great, there will be no sparks or arc formed between the two plates for the time being. If, however, the sheets are approached, as is unavoidable for the purpose of final union by pressing, hammering, etc., as already explained, a time must arrive when the air resistance between the two sheets to be welded is no longer sufficiently great to prevent equalization of the electricity at the two poles. Between the sheets, therefore, an arc or a line of sparks will be formel, and will continue until intimate contact has taken place between the two sheets. If, as shown in Fig. 1, the sheets are relatively thick, the arc which is formed will be of no consequence, since the slight fusing away at 4 caused by the arc, or the sparks, will not be sufficiently deep to penetrate the thick material. In fact there is even an advantage in the action of the sparks or arc in the case in question, since the cross section of the material is altered, whereby the two sheets are, as it were, scarfed at the place of welding, that is to say, the two cross sections are diminished at the seam to approximately the thickness of a single sheet, so that under certain conditions the two welded sheets have the same thickness at the joint as a single sheet.

"The case is altogether other when two thin sheets or articles are to be welded, or when a very thin object is to be welded to a thicker one, such as is shown, for instance, in Fig. 2. In this Figure it is assumed that the thick sheet 2 (which, as explained with reference to Fig. 1, is thick enough not to be penetrated completely by the arc at the point 4) is to be electrically welded to a very thin plate 5 by the ordinary process as above explained.

"On the approach of the objects 2, 5, at a certain moment, in consequence of the penetration of the layer of air 3, fusing away takes place at 4, owing to the arcs or sparks, and this fusing will extend to such depth that, although, as above explained, not injurious in the case of the sheet 2, it causes the thin sheet 5 to be completely perforated or burnt through. Thus the ordinary process of welding by means of an arc is quite impracticable with thin sheets.

"The essential feature of my invention is that in welding thin sheets the formation of such an arc, or sparking distance, which proves so disastrous, is wholly avoided, whereby a perfectly sound welded joint between such bodies, or between a very thin body and a thicker object, is attained.

"For the purpose of preventing the formation of the injurious arc, that is to say the sparking distance, I first submit the superposed metal objects to be welded 5, 6 (Figs. 4 and 5) to a certain pressure, the amount of which will depend upon the nature of the objects. This pressure I effect by means of the electrodes a b (Figs. 4 and 5) themselves, or with the aid of other suitable means."

The last quotation, except as to the last twelve lines, contains the matter alleged by Rietzel to constitute a disclaimer of the subject-matter of the interference issues, the contention being that the claims constituting the counts are of sufficient scope as to include the process of the disclaimer; that Harmatta has disclaimed the counts to that extent and consequently the claims in their entirety and hence he has no right to make such claims.

In considering this question it is necessary to ascertain exactly what, if anything, Harmatta did disclaim, for he cannot be presumed to have made a disclaimer unless the terms and the subject are so clear as to be practically indisputable.

The only disclosure in the alleged disclaimer, so far as it relates to the issues, that appears to be stated with certainty is, that electrodes contacting with the plates to be welded are used, and that the process to which Harmatta refers as "common" does not really differ from the ordinary method of welding at the fire. In such case he would apparently refer to ordinary welding wherein the parts are heated by an electric current to a welding temperature and then pressed or hammered together, this being analogous to the case where a workman heats two pieces together to a welding temperature and then welds them on an anvil. Hence, viewed from such a point, Harmatta cannot be said to have disclaimed the subject-matter of the interference counts, for should such be held, it would place such counts in the class of cases where in the invention is disclosed in many patents on ordinary fire welding and also in many prior patents on electric welding. If the claims are to be subjected to a scrutinizing interpretation to ascertain whether or not they are of such scope as to be anticipated by such patents the motion would be resolved into an allegation of non-patentability in view of the general state of the art; but as the motion alleged no such ground, such question of non-patentability cannot now be passed upon. Moreover, these counts, in their present terms, were allowed in the patent to Rietzel and it is to be assumed that the Examiner then in charge of the case duly considered the question of patentability and the fact of the allowance of the claims indicates either that he considered them clearly patentable or that the question of anticipation was not so clear in his mind as to warrant his rejection of them.

Furthermore to consider the counts specifically the following conditions are found.

Count 1 calls for electrically welding the plates at spots only by the application of pressure and heating current localized in such spots.

The disclaimer does not in any event disclose specifically the welding together of the pieces at *spots only* by the application of pressure and heating current *localized in such spots.*

Count 2, inter alia, calls for *the simultaneous application of current and pressure.*

This is not found in the disclaimer.

Count 3 falls in the same class as count 1.

Count 4 is specific to an article composed of metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of such plates being practically unaltered in their metallic condition and the spots on their meeting surfaces being separated from one another by distinct unwelded areas.

No such specific character of article is found in the disclaimer.

Counts 5, 6, 7 and 8, like count 4, contain mention of specific details not to be found in the disclaimer.

Careful consideration has been given to the decision *Ashcroft vs. Boston and Lowell Railroad* 97 U. S. 189, but it is not seen to have any bearing on the case in support of the motion. In this case the patentee, Naylor, obtained a British patent in which he stated that he made no claim to a certain construction, definitely specifying the same. He also obtained a patent in the United States, which patent was reissued, the reissue patent being that on which suit was brought. The Court held that the disclaimer in the British patent held good even in a suit on a patent in this country; and furthermore the Court considered that the disclaimer was made in view of another British patent, (to Beyer) wherein was found the disclaimed matter.

No such condition is found in the Harmatta application. The disclaimer is not sufficiently definite to be determined with certainty. Nor is any art disclosed which would indicate the subject-matter of the disclaimer.

In conclusion, it may be said that the decision of the Court of Appeals of the District of Columbia in *In re Orcutt* 141 O. G. 567, C.D., 1909, 334 appears to have an important bearing on this motion. In that case the conditions were very similar to those of the present interference. Orcutt's application was involved in an interference with a patent to McDonald and McDonald, granted during the pendency of Orcutt's application. After the patent was granted Orcutt copied claims therefrom and obtained an interference. Priority was awarded by the Examiner of Interferences to McDonald and McDonald. On appeal by Orcutt, the Examiners-in-Chief did not pass upon the question of priority but stated to the Commissioner under Rule 126 that they considered the claims unpatentable. The Primary Examiner, on reference, rejected the claims, which rejection was affirmed by the Commissioner. On appeal to the Court of Appeals, while the rejection was affirmed, the Court said:

> "In view of the inadvertence of the Patent Office in granting a patent to McDonald and McDonald for the claims of the issue, which patent is now beyond the control of the Office, it would probably have been the more equitable practice to have assumed patentability in the interference proceeding for the purpose of determining the question of priority between the two parties thereto. However, it was within the scope of the

Commissioner's authority to dissolve the interference, if convinced that the issue was not patentable. Should we declare the rejected claims patentable, the result would be that an interference would again be declared and the question of priority determined. It will thus be seen that the decision of the Commissioner dissolving the interference did not preclude Orcutt, if there was merit in his claims, from ultimately contesting the question of priority with the patentees, McDonald and McDonald."

Here we have a condition very analogous in some points to that of the present case. An applicant was involved in an interferece with a patent granted on a copending application. The question of patentability was raised (by the Examiners-in-Chief) after a decision of priority by the Examiner of Interferences; the anticipation was so clear as to cause a rejection of the claims by every tribunal; and yet, in their decision rejecting the claims, the Court stated that it would probably have been more equitable, under the circumstances, to have had a judgment of priority before the question of non-patentability was raised.

In the present case the question is not clear as to what is covered by the disclaimer, but even if less doubtful than it is, it would be contrary to the dictum of the decision quoted to dissolve the interference.

In regard to the motion made by Harmatta to add counts under the provisions of Rule 109, these counts being claims 2, 3 and 4 of Rietzel's patent, it is not seen why he is not as much entitled to make such claims as he was to make the claims now involved in the interference, they reading as well on his disclosure as the others.

The motion made by Rietzel to dissolve is denied.

The motion made by Harmatta to add additional claims under Rule 109 is granted.

No appeal lies from either part of this decision.

No. 31,792.

In re Interference:

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

MOTION.

NOW COMES Adolph F. Rietzel by his attorneys and moves for a rehearing of his Motion to Dissolve the Interference decided by the Examiner June 5th 1911 upon the grounds:—

1. That a question decisive of the case and duly argued by counsel was overlooked, to wit:

The question whether the British patent of Harmatta describes as an old method of welding, a process within the broad terms of the issue of this interference.

2. There was obvious misapprehension in treating the description of the Harmatta United States specification in the part disclosing the alleged disclaimer as being a reference to ordinary fire welding since in view of the context and the object of the invention said description can only refer to a process of electric welding and to one wherein the electric current is applied at a time with reference to the application of pressure, such as to produce what the applicant describes as a line of sparks or an arc.

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

AFFIDAVIT.

To the Hon. Com. of Patents.
Sir:—

C. Hugh Duffy, being duly sworn deposes and says that he is of counsel for Johann Harmatta in the matter of the above entitled interference; that on June 14th 1911 affiant mailed to the Berlin agents of Johann Harmatta preliminary statement as to counts 9, 10 and 11 to be signed and executed by the said Harmatta; and that affiant is this day in receipt of a cablegram from the said Berlin agents of the said Harmatta requesting an extension of time for the filing of said preliminary statement as per Exhibit I attached hereto; that affiant is without direct advice as to the reason of said request for extension, but believes that the said Harmatta is away from the German Empire and therefore connot be reached in time to execute the said preliminary statement and have same on file by the 14th of August 1911; that this motion is made in good faith and not for the purposes of delay.

C. HUGH DUFFY,
Of Counsel for Harmatta.

RIETZEL

vs.

HARMATTA.

Please find below a communication from the Examiner in charge of Interferences in regard to the above-cited case.

Very respectfully,

E. B. MOORE,
Commissioner of Patents.

6—1652

On August 3, 1911, a motion was filed by Harmatta to extend the time for filing preliminary statements as to counts 9, 10, and 11, to September 15, 1911.

The record shows that on August 8, 1911, the parties entered into a stipulation agreeing to the extension asked by the motion. The stipulation is hereby approved and the time for filing preliminary statements in so far as the counts mentioned therein is concerned is extended to September 15, 1911.

In view of the approval of the stipulation no action upon the motion is necessary, and the motion is therefore dismissed.

RIETZEL

vs.

HARMATTA.

PRELIMINARY STATEMENT OF JOHANN HARMATTA.

Johann Harmatta of Szepesváralja, in the Kingdom of Hungary, being duly affirmed, deposes and says that he is a party for the interference declared by the Commissioner of Patents on April 26th 1910 between his application for the United States for ELECTRIC WELDING, Serial No. 183,677, filed December 3rd 1903, and the patent to Adolph F. Rietzel, UNITING THE COMPONENT PARTS OF COMPOSITE SHEET METAL STRUCTURES, No. 928,701, patented July 20th 1909; that he conceived the invention set forth in the interference and the invention as defined by the three claims 10, 11 and 12 which are attached hereto and made a part hereof at the end of the year 1900 without having had then the opportunity of carrying out the invention disclosed in said claims 10, 11 and 12 for lack of time; that on or about the 15th day of September 1901, as he set working his own manufactory at Szepesváralja he first made drawings of the device for carrying out the process set forth in the said claims 10, 11 and 12; that in the first days of October 1901 he modified an old chain-welding machine so as to be able to carry out the process as set forth in the said claims 10, 11 and 12; that on the 15th up to the 20th day of October 1901, he had thin iron sheets welded and attachments welded upon sheet metal vessels successfully and on a manufacturing scale by his workmen Michael Hozza and Michael Tomaskiewicz, with the help of the process forming the object of the said claims 10, 11 and 12; said two workmen, who live here at Szepesváralja and who remember very well to have performed the said work at the mentioned time, being ready to give testimony in respect of the above facts; that in the course of November 1901 he mentioned said electric weldings of thin iron sheets to Mr. Hegenscheidt, Director General of the firm "Oberschlesische Eisen-

industrie A.G." (Upper Silesian Iron Industry Company of shareholders) at Gleiwitz, Silesia, Germany, in the presence of the Chief-Engineer of said Mr. Hegenscheidt, Mr. Wilhelm Fischer, who is at present Director, and that said gentlemen promised to inform the firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz, Silesia, Germany, about the said electric weldings of thin iron sheets; that the firm "Eisenhütte Silesia" received said information from said gentlemen, but raised doubts about the possibility of electrically welding such thin iron sheets without danger of burning through said metal sheets; that said firm "Eisenhütte Silesia", for the sake of verification, sent during the summer of the year 1902, to him (Harmatta) several blanks of sheet metal utensils, which he (Harmatta) welded, with the help of the process forming the object of said claims 10, 11 and 12, to the thorough satisfaction of said "Eisenhütte Silesia"; that when Mr. Schweisfurth of Paruschowitz, technical Director of the firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz, Silesia, Germany, came to him in order to look at the electric weldings and the modified chain-welding machine; and, as said Mr. Schweisfurth had convinced himself by ocular proof that it is very easy to weld such thin iron sheets with the help of the process forming the object of the said claims 10, 11 and 12, the said firm "Eisenhütte Silesia" (Silesia Iron Works) at Paruschowitz acquired the property of said process by a contract made with him (Harmatta) at the date of February 12th, 1902; and that from the month of January 1903 a great number of full-size machines adapted to carry out the welding process forming the object of said claims 10, 11 and 12 have been manufactured by said "Eisenhütte Silesia" for personal use and sale to others; the first new and full-size machine of this kind having been completed in the last days of January 1903 and first successfully operated and used in February 1903 for carrying out his process, in the works of the "Eisenhütte Silesia", in the village of Paruschowitz, Silesia (Germany).

That patents for such invention were applied for and obtained as follows:

Application filed in Germany, March 24th, 1903, published June 20th, 1904, patent not granted;

application filed in Sweden, October 12th, 1903, patent dated October 12th, 1903, No. 24035; published the 16th day of November 1907 and granted the 23rd day of January 1908;

application filed in France, October 13th, 1903, patent dated October 13th, 1903, No. 336187; published the 1st Day of March 1904 and granted the 7th day of January 1904;

application filed in Austria, October 14th, 1903, patent dated August 1st, 1905, No. 24335; published the 8th day of January 1905 and granted the 30th day of March 1906;

application filed in Denmark, October 14th, 1903 published May 16th, 1905, patent not granted;

application filed in Luxemburg, October 14th, 1903, patent dated October 15th, 1903, No. 5300; published the 14th day of October 1903 and granted the 14th day of October 1903;

application filed in Hungary, October 15th, 1903, patent dated October 15th, 1903, No. 31382; published the 29th day of April 1904 and granted the 24th day of August 1904;

application filed in Switzerland, October 15th, 1903, patent dated October 15th, 1903, No. 29723; published June 21st, 1905 and granted the 21st day of June 1905;

application filed in Belgium, October 16th, 1903, patent dated October 16th 1903, No. 173119; published the 20th day of January 1904 and granted the 31st day of October 1903;

application filed in Russia, October 20th, 1903, patent not granted;

application filed in Spain, October 20th, 1903, patent dated December 10th, 1903, No. 32726; published the 10th day of December 1903 and granted the 10th day of December 1903;

application filed in Italy, October 22nd, 1903, patent dated October 22nd, 1903, No. 180/117; published the 16th day of December 1903 and granted the 16th day of December 1903;

application filed in Great Britain, October 23rd, 1903, patent dated October 23rd, 1903, No. 22981/1903; published the 20th day of October 1904 and granted the 25th of August 1904;

application filed in Canada, December 4th, 1903, patent not granted;

application filed in Canada, December 4th, 1903, patent not granted;)

application filed in Japan, December 14th, 1903, patent dated April 6th, 1905, No. 8640; published the 6th day of April 1905 and granted the 6th day of April 1905;

application filed in Romania, July 11th, 1906, patent not granted;

That such invention was fully described in the following patent specifications; Sweden No. 24035; France No. 336187; Austria No. 24335; Hungary No. 31382; Switzerland No. 29723; Great Britain No. 22981/1903; Japan No. 8640.

The knowledge of such invention was first introduced in the United States on December 3rd, 1903 by the papers belonging to said U. S. application of Harmatta, serial number 183,677, for "Improvements in Electric Welding", filed December 3rd, 1903, said application papers having been sent by applicant to Messrs. Marion & Marion at Montreal, Canada, who filed said application to the United States Patent Office on December 3rd, 1903.

RIETZEL

vs.

HARMATTA.

Statement of Rietzel.
Filed Sept. 14, 1911.
Approved " 22, 1911.

PRELIMINARY STATEMENT OF ADOLPH F. RIETZEL AS TO COUNTS 9, 10 AND 11.

State of Connecticut, County of New London, ss.:

ADOLPH F. RIETZEL, of Charlestown, County of Washington and State of Rhode Island, being duly sworn, doth depose and say that he is a party to the interference declared by the Commissioner of Patents on the 26th day of April, 1910, between the patent of Adolph F. Rietzel, No. 928,701, dated July 20th, 1909, and an application for a similar invention filed by Johann Harmatta, the interference issue being amended June 12, 1911 by adding counts 9, 10, and 11.

That he conceived the invention set forth in the added counts 9, 10 and 11 during the latter part of October or first part of November 1897;

That, as near as deponent can at this time fix the date, the invention set forth in said added counts was successfully reduced to practice in the latter part of July 1898, and at the same time was first explained and disclosed to others;

That sketches of the application of the invention were made in the early part of June 1904 and from time to time since that date innumerable sketches have been made of the invention as applied to various articles of manufacture;

That the invention has been put to very extensive use in the manufacture of numerous sheet and other metal work of various kinds.

In re Interference:

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

No. 31,792.

MOTION TO DISSOLVE.

NOW COMES ADOLPH F. RIETZEL, a party to the above entitled Interference, by his attorneys, and moves that the Interference as regards counts 9, 10 and 11 be dissolved on the following grounds:

FIRST: That the party Harmatta has no right to make the claims forming the subject of the Interference for the reason that he disclaimed the subject-matter of the counts of the Interference in his substitute specification filed May 14th 1904, beginning with the paragraph "As Fig. 1 shows" on page 2 and again repeated the disclaimer by his amendment to said specification filed May 18th 1906, and he did not withdraw said disclaimer by merely complying with the Examiner's requirement when he insisted on said requirement that "the description should be confined to applicant's process of welding and not to a discussion of prior processes and their disadvantages."

SECOND: That the party Harmatta has no right to make the claims forming the subject of the Interference for the reason that there is no patentable difference between carrying out any process of welding by applying pressure before and during the period of supplying the electric current and by applying pressure only at the moment of the electric current supply as stated at lines 4 to 10 on page 1 of Harmatta's original specification, and the applicant Harmatta by his amendments eliminating the method consisting in applying pressure only at the moment of current supply has disclaimed that method as his invention and therefore has no right to make any claim founded upon the use of pressure and current.

Rietzel on October 17, 1911, presented a motion to transmit a motion to dissolve.

The motion is directed only to counts 9, 10 and 11, which counts were added to the interference by a redeclaration thereof on June 13, 1911.

It is well settled that motions to dissolve will not be transmitted with respect to counts which have been added under the provisions of Rule 109, where the parties have had full opportunity to raise any questions which may be raised upon motion to dissolve. In fact, Rule 109 as it now stands specifically states that such motion will not be transmitted.

The motion to transmit is denied.

Limit of appeal: November 3, 1911.

The taking of testimony is suspended.

RIETZEL

vs.

HARMATTA.

INTERFERENCE NO. 31,792.

BRIEF FOR HARMATTA ON RIETZEL'S APPEAL FROM THE EXAMINER OF INTERFERENCES DENIAL OF A MOTION TO TRANSMIT A MOTION TO DISSOLVE AS TO ADDED COUNTS.

Honorable Commissioner of Patents.

Sir:

This case comes before your Honor on appeal by Rietzel from a decision of the Examiner of Interferences, dated October 20, 1911, denying a motion to transmit a motion to dissolve with respect to counts (9, 10 and 11) added to the interference in a redeclaration thereof by the Primary Examiner June 13, 1911.

This interference was declared April 14, 1910, and involved eight claims of Rietzel's patent No. 928,701, dated July 20, 1909.

Rietzel's application was filed February 24, 1905.

Harmatta's application was filed December 3, 1903.

Preliminary statements were duly filed on behalf of both parties

Under date of September 9, 1910, Rietzel filed a motion for dissolution of the interference, setting up three grounds, which are as follows:

"FIRST, that the party Harmatta has no right to make the claims forming the subject of the interference for the reason that he disclaimed the subject matter of the counts of the interference in his substitute specification filed May 14, 1904, beginning with paragraph 'As Figure 1 shows,' on page 2, and again repeated the disclaimer by his amendment to said specification filed May 18, 1906, and he did not withdraw said disclaimer by merely complying with the Examiner's requirement when he inserted, on said requirement, that 'the description should be confined to applicant's process of welding, and not to a discussion of prior processes and their disadvantages.'

"SECOND, that the party Harmatta has no right to make the claims forming the subject of the interference for the reason that there is no patentable differences between carrying

out any process of welding by applying pressure before and during the period of supplying electric current, and applying pressure only at the moment of the electric current supply, as stated in lines 4-10 on page 1 of Harmatta's original specification, and the applicant Harmatta by his amendments eliminating the method consisting in applying pressure only at the moment of current supply has disclaimed that method as his invention, and therefore has no right to make any claim found upon the use of pressure and current.

"THIRD, that the party Harmatta has no right to make the claims forming the subject of counts 4, 5, 6, 7 and 8 of the issue of this interference for the reason that he has not filed the oath required by the Rule 48 and the Patent Statutes."

Under date of September 17, 1910 the Examiner of Interferences transmitted the motion as to the first two grounds, but denied it as to the third, following the practice, which is that the question of the sufficiency of the oath, either original or supplemental, is an ex parte matter which may be adjudicated after determination of the contest.

Under date of September 23, 1910 Rietzel appealed from this denial of his third ground.

Under date of November 23, 1910 Rietzel appealed from this denial of his third ground.

Under date of November 23, 1910 the Commissioner of Patents affirmed the decision of the Examiner of Interferences.

Under date of December 28, 1910 Rietzel asked for a re-hearing of his appeal.

Under date of December 29, 1910 the petition for re-hearing was denied.

Under date of December 14, 1910 Rietzel's motion for dissolution was set for hearing before the Primary Examiner as of the date January 5, 1911.

By stipulation this hearing was postponed until Thursday, February 2, 1911.

On January 7, 1911, Harmatta moved to add claims 2, 3 and 4 of the Rietzel patent in interference to the present issues, as counts 9, 10 and 11, which motion was duly transmitted under date of January 14, 1911, by the Examiner of Interferences.

Under date of January 18, 1911 the Primary Examiner set the motion of Harmatta to amend as of the date February 2, 1911, being the same time that had been set for Rietzel's hearing on his motion to dissolve.

Under date of January 18, 1911 Rietzel appealed from the ruling of the Examiner of Interferences transmitting the motion to amend brought by Harmatta to the Commissioner of Patents.

Under date of January 26, 1911 the Commissioner affirmed the decision of the Examiner of Interferences transmitting Harmatta's motion to amend.

After these various motions, and under date of February 2, 1911, this case was heard, both on Rietzel's motion to dissolve, and Harmatta's motion to amend, full argument being accorded both sides, and all of the questions raised by the motions were considered.

Under date of June 5, 1911, the Primary Examiner denied Rietzel's motion to dissolve, and granted Harmatta's motion to amend.

Under date of June 9, 1911, Rietzel moved to re-hear on the motion to dissolve.

Under date of June 12, 1911, the Primary Examiner denied the motion for re-hearing, and under the same date re-declared the interference, adding counts 9, 10 and 11 presented by Harmatta.

Harmatta, under date of September 12, 1911, filed his additional preliminary statement with respect to counts 10, 11 and 12.

Under date of September 14, 1911, Rietzel filed his statement as to the added counts.

Under date of September 25, 1911 the times for taking testimony was fixed.

Under date of October 17, 1911, Rietzel brought a motion to dissolve the interference as to counts 9, 10 and 11, alleging that the party Rietzel had had no hearing with respect to the question of the right of Harmatta to make the counts 9, 10 and 11, since the original motion for dissolution embraced the original eight counts of the issue.

This is the chronology of the actions in this case.

The ruling of the Examiner of Interferences in this case was correct.

Rule 109 provides that a party to an interference may amend his application by filing claims which, in his opinion should be made the basis of an interference between himself and other parties, and that on admission of such amendment the interference will be re-declared. Rule 109 finally points out that

> "Motions for dissolution will not be transmitted in regard thereto (i. e. the added claims) where the questions raised could have been disposed of in connection with the admission of the claims." (Paren's ours.)

So far as Harmatta is advised this is the rule of practice, and if it is, Rietzel is without standing in his attempt to transmit a motion for dissolution with respect to these added counts to the Primary Examiner.

The record of his case, as given above, shows that this interference has been pending since April 14, 1910, and for over a year and a half has been through a series of motions and appeals, all of which, with the exception of Harmatta's motion to amend, were initiated by Rietzel.

The record further shows that Harmatta, on January 7, 1911, moved to add these claims to the interference.

It seems absurd in the extreme for Rietzel to come in at this late

day and argue that he has had no opportunity to be heard on Harmatta's motion to add the counts, when the record shows that the Primary Examiner advised the parties that on February 2, 1911 the motions of Rietzel to dissolve, and of Harmatta to amend would be heard.

On that day (February 2, 1911) the parties were heard, and both the motion to dissolve, and the motion to amend were presented.

As the result of that hearing the motion to dissolve was denied, and the motion to amend was granted, so that for nearly a year Rietzel has been advised of Harmatta's motion to amend, he has had full opportunity to contest it, and in fact did contest it before the Examiner of Interference, and afterwards by appeal to the Commissioner when the Examiner of Interferences transmitted the motion to amend.

It comes with poor grace at this late day on the part of Rietzel to advance the childish argument that he has had no hearing upon the question of Harmatta's right to make the claims 9, 10 and 11.

On the contrary the present case shows a multiplicity of dilatory motions and appeals on behalf of Rietzel, the moving party, his tactics seeming rather such as seek delay than a speedy settling of the case on proofs and final hearing.

The decision relied on by the moving party, Rietzel, is without force for the reason that that ruling was made prior to the amendment of Rule 109, and it has been held in the decision of Gibson vs. Kitsee, 1909, C. D. 146 that the refusal to transmit motions to dissolve with respect to counts added under Rule 109 is in accord with the terms of that Rule, 109, which expressly prohibits the transmission of such a motion.

This was held in a case where the moving party alleged surprise at the Primary Examiner's decision and would seem to settle the present case beyond question, because Rietzel can set up no reason why the Rule, 109, should be disregarded, or its application modified.

Respectfully,
O. E. Duffy & Son,
Attorneys for Harmatta.

ADOLPH F. RIETZEL

vs.

JOHANN HARMATTA.

INTERFERENCE No. 31,792.

BEFORE THE HONORABLE COMMISSIONER OF PATENTS ON APPEAL FROM THE DECISION OF THE EXAMINER OF INTERFERENCES.

BRIEF FOR RIETZEL.

This case comes up on appeal by the party Rietzel from the decision of the Examiner of Interferences dated October 20th 1911, refusing to transmit to the Primary Examiner the motion to dissolve brought by Rietzel.

This motion relates to counts 9, 10 and 11 and is a substantial duplicate of the motion to dissolve previously brought with regard to the counts 1, 2, 3, 4, 5, 6, 7 and 8, the counts 9, 10 and 11 having been added since the bringing of that motion.

This motion should be heard and decided by the Primary Examiner as it does not anywhere appear in the record of this case that said Primary Examiner has considered the relation of the alleged disclaimer to the counts 9, 10 and 11, the Examiner stating in his decision dated June 5th 1911, by which the counts 9, 10 and 11 were permitted to be added, that Harmatta could make these claims for the reason that they read as well on his disclosure as the other claims, and it does not appear that the Examiner in any way considered the disclaimer with relation to these added counts or that Harmatta was entitled to make these claims in view of the alleged disclaimer made the subject of the present motion.

It is for the purpose of securing a definite decision upon this point that the present motion to dissolve should be transmitted and decided and the party Rietzel respectfully calls the Commissioner's attention to his Brief filed in connection with the motion for transmission heard before the Examiner of Interferences on the 20th day of October, 1911.

TOWNSEND & DECKER,
Attorneys.

RIETZEL

vs.

HARMATTA.

PATENT INTERFERENCE No. 31,792.

APPEAL ON MOTION.

ELECTRIC WELDING.

Patent granted Adolph F. Rietzel July 20, 1909, No. 928,701, on application filed February 24, 1905.
Application of Johann Harmatta filed December 3, 1903, No 183,677.

Messrs. Townsend & Decker for Rietzel.
Messrs. O. E. Duffy & Son for Harmatta.

This is an appeal by Rietzel from the decision of the examiner of interferences refusing to transmit a motion to dissolve the interference as to certain claims which were made the issue of the interference by virtue of a motion to add them, under the provisions of Rule 109.

It is well settled that when a motion is brought to add claims under the provisions of Rule 109, each of the parties must present before the Primary Examiner all the reasons affecting the question of the propriety of the insertion of the claims, and the consequent amendment of the issue in interference. It would only tend to delay proceedings to hear and determine a motion to add claims under Rule 109, and subsequently to transmit, hear and determine a motion to dissolve the interference as to the very claims added under the prior motion. The propriety of including these claims in the issue was affirmatively and finally decided upon the motion brought under Rule 109.

The Examiner of Interferences is right in refusing to transmit the present motion to dissolve and his decision is affirmed.

C. C. BILLINGS,
First Assistant Commissioner.

The First Assistant Commissioner having affirmed the decision of the Examiner of Interferences denying transmission of the motion for dissolution, filed by Rietzel on October 17, 1911, proceedings are this day resumed and times for taking testimony and for final hearing are reset as follows:

Rietzel's testimony in chief to close Feb. 9, 1912.
Harmatta's testimony to close March 11, 1912.
Rietzel's rebuttal testimony to close March 26, 1912.
Final hearing: May 28, 1912, at 11 A.M.

AFFIDAVIT.

District of Columbia, ss:

CHARLES F. TISCHNER, JR., being duly sworn, deposes and says that he is a member of the firm of Townsend & Decker, attorneys for the party Rietzel in the above-entitled interference; that deponent has this case in his personal charge; that for upwards of six months past negotiations have been pending for a settlement of the interference between the parties; that since the early part of December, 1911, and until about a week ago, deponent has been away from his office and, except for the time consumed in travel, has been in Berlin, Germany, negotiating for the purchase of the Harmatta invention involved in this interference for and on behalf of the owners of the Rietzel patent; that owing to such negotiations it has been impossible to take any testimony on behalf of Rietzel; that papers have been executed transferring the Harmatta application involved in this interference to the Thomson Electric Welding Co., owner of the Rietzel patent, but that such papers have not yet been received in this country; that, according to deponent's best knowledge and belief, such papers are now in

transit and should arrive within a short time; that it is desired to take testimony in the interference on behalf of the party Rietzel; that it is expected that such testimony can and will be taken and completed within the sixty days' extension of time now requested, and that the request is made in good faith and not for the purposes of delay.

CHAS. F. TISCHNER, JR.

DEPARTMENT OF THE INTERIOR.

UNITED STATES PATENT OFFICE.

To all persons to whom these presents shall come, Greeting:

THIS IS TO CERTIFY that the annexed is a photographic copy from the record of this office of an instrument of writing

Recorded April 5, 1912,

in

Liber A-ov, page 311.

Said record has been carefully compared with the original and is a correct transcript of the whole thereof.

IN TESTIMONY WHEREOF I have hereunto set my hand and caused the seal of the Patent Office to be affixed at the City of Washington, this 17th day of March, in the year of our Lord one thousand nine hundred and nineteen and of the Independence of the United States of America the one hundred and forty-third.

Acting Commissioner of Patents.

1919

Assignment

WHEREAS, I, JOHANN HARWATTA, of Szombathely, Hungary, invented certain new and useful improvements in Electric Welding set forth in a certain application for letters patent of the United States, which application was filed in the United States Patent Office on or about the 3rd day of March 1903 and bears S. N. 143,677; and

WHEREAS, the THOMSON ELECTRIC WELDING COMPANY, a corporation duly organized and existing under the laws of the State of Massachusetts and having an office in the City of Lynn, Mass., is desirous of acquiring the said invention application for patent and Letters Patent to be granted for the same in and for the United States;

NOW THEREFORE, To All Whom It May Concern

Be it known that, for and in consideration of the sum of One (1) Dollar to me in hand paid by the THOMSON ELECTRIC WELDING COMPANY and other good and valuable consideration, the receipt of which is hereby acknowledged, I, the said JOHANN HARWATTA, have sold, assigned, transferred and set over and by these presents do sell, assign, transfer and set over unto the THOMSON ELECTRIC WELDING COMPANY, its successors and assigns, the entire right, title and interest in and

to the said invention, application for patent and Letters Patent to be issued for the same in and for the United States, the said invention, application for patent and letters patent together with any reissue or reissues or extension or extensions of the same to be held and enjoyed by the said THOMSON ELECTRIC WELDING COMPANY for its own use and behoof and for the use and behoof of its successors, assigns or other legal representatives to the full end of the term for which said

letters patent are or may be granted, reissued or extended. And I do hereby authorize and request the COMMISSIONER OF PATENTS of the UNITED STATES to issue the letters patent for said invention to the THOMSON ELECTRIC WELDING COMPANY as the sole owner thereof.

And I do further covenant and agree that I will render the said THOMSON ELECTRIC WELDING COMPANY, its successors, assigns or other legal representatives all assistance within my power to secure the grant of a patent or patents for said invention and that I will upon request execute all oaths or other papers which may be required or deemed necessary to obtain said patent or patents necessary in connection therewith.

And I do further covenant and agree that I will, at any time upon request, communicate to said THOMSON ELECTRIC WELDING COMPANY, its successors, assigns or other legal representatives, any facts relating to said invention and letters patent or the history thereof known to me and testify as to the same when requested to do so by the said THOMSON ELECTRIC WELDING COMPANY but at the expense of said Company for said services.

And I do further covenant and agree that should it be desired or necessary to file a division of said application that I will upon request sign and execute such application papers and do all other lawful acts as may be necessary to apply for patent for such divided matter without further compensation but at the expense of said assignee.

IN TESTIMONY WHEREOF, I have hereunto set my hand and affixed my seal at the City of Berlin, Germany, this Berlin day of 3 Febr. 1912.

IN TESTIMONY WHEREOF I have hereunto set my hand and caused the seal of the Patent Office to be affixed at the City of Washington, this 31st day of March, in the year of our Lord one thousand nine hundred and nineteen and of the Independence of the United States of America the one hundred and forty-third.

Acting Commissioner of Patents.

1952 114

A S S I G N M E N T .

WHEREAS, I, ADOLPH F. RIETZEL, have invented certain new and useful improvements in Method of Electric Welding, which are set out in a certain application for Letters Patent of the United States, filed by me in the United States Patent Office, on the 24th day of February 1905, Application S. N. 247,081 and

WHEREAS, the THOMSON ELECTRIC WELDING COMPANY, a corporation organized and existing under the laws of the State of Maine, and having an office at Lynn, in the State of Massachusetts, is desirous of acquiring the entire right, title and interest in and to the said invention, for the whole world, and in and to the Letters Patent to be issued for the same in the United States and all other countries:

NOW, THEREFORE, To All Whom It May Concern: Be it known that for and in consideration of the sum of One ($1.00) Dollar to me in hand paid, by the said THOMSON ELECTRIC WELDING COMPANY, and other good and valuable consideration, the receipt of which is hereby acknowledged, I, the said ADLPH

F. RIETZEL, have sold, assigned, transferred and set over, and by these presents, do sell, assign, transfer and set over unto the said THOMSON ELECTRIC WELDING COMPANY, its successors and assigns, the entire right, title and interest in and to the invention and application for patent in and for the United States, and all other countries, the said invention and the Letters Patent to be issued for the same, together with any reissue or reissues or extension or extensions of said Letters Patent to be held and enjoyed by the said THOMSON ELECTRIC WELDING COMPANY, its successors, assigns or other legal representatives, for its own use and behoof, and for the use and behoof of its successors, assigns or other legal representatives, to the end of the term or terms for which said Letters Patent are or may be granted, reissued or extended, as fully and entirely as the same would have been held and enjoyed by me had this assignment and sale not been made. And I do hereby authorize and request the Commissioner of Patents of the United States to issue the Letters Patent for said invention to the said Company as the sole owner thereof.

And I do hereby further authorize the said THOMSON ELECTRIC WELDING COMPANY to apply for and obtain patents in its own name in all other countries, and to sign for me and in my name whenever it may be necessary, all papers requisite for applying for and obtaining Letters Patent in any foreign countries.

And I do further covenant and agree that I will execute such further application papers, powers of attorney or other instruments in writing as may be necessary to enable said Company to obtain foreign Letters Patent either in my or in its own name, or to vest in said Company the entire right, title and interest in said invention and any Letters Patent therefor.

And I do hereby covenant that I have full right to convey the entire interest herein assigned, and that I have not executed, and will not execute, any agreement in conflict therewith.

And I further hereby covenant and agree that I will, at any time, upon request, execute and deliver any and all papers that may be necessary or desirable to perfect the title to said invention or Letters Patent of the

United States, in said THOMSON ELECTRIC WELDING COMPANY, its successors, assigns or other legal representatives, and that if said THOMSON ELECTRIC WELDING COMPANY, its successors, assigns, or other legal representatives, desire to secure a reissue or extension of such Letters Patent, or that a disclaimer relating thereto should be filed, that I will, upon request, sign all papers, make all rightful oaths, and do all lawful acts requisite for the application for such reissue or extension and the procuring thereof and for the filing of such disclaimer, without further compensation, but at the expense of said assignee, its successors, assigns or other legal representatives.

And I do further covenant and agree that I will, at any time, upon request, communicate to said THOMSON ELECTRIC WELDING COMPANY, its successors, assigns, or other legal representatives, any facts relating to said invention and Letters Patent, or the history thereof, known to me, and testify as to the same in any interference of other litigation when requested to do so. while employed by said Thomson Electric Welding Co

written before being signed IN TESTIMONY WHEREOF, I have hereunto set my hand and affixed my seal at Lynn Mass. this 23rd day of March 1905.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE.

To all persons to whom these presents shall come, Greeting:

THIS IS TO CERTIFY that the annexed is a true copy from the records of this office of an instrument of writing

Recorded July 19, 1910,

in

Liber S-84, pages 292 and 294.

Said record has been carefully compared with the original and is a correct transcript of the whole thereof.

IN TESTIMONY WHEREOF I have hereunto set my hand and caused the seal of the Patent Office to be affixed at the City of Washington, this 10th day of May, in the year of our Lord one thousand nine hundred and nineteen and of the Independence of the United States of America the one hundred and forty-third.

J. T. NEWTON,
(Seal) *Commissioner of Patents.*

S84—292.

WHEREAS on March 8, 1910 the stockholders of the Thomson Electric Welding Company, a corporation organized under the laws of the State of Maine, voted to sell and transfer all its assets and property, both real and personal, of every nature to the Thomson Electric Welding Company, a corporation organized under the laws of the Commonwealth of Massachusetts, a copy of which vote is hereto annexed; and

WHEREAS all the acts and things required to be done before such transfer have been done;

NOW, THEREFORE, the said Thomson Electric Welding Company of Maine in consideration of the premises and of one dollar and other valuable consideration to it paid by said Thomson Electric Welding Company of Massachusetts, the receipt whereof is hereby acknowledged, does hereby give, grant, bargain, sell, transfer, assign and convey unto the said Thomson Electric Welding Company of Massachusetts, all its property, both real and personal, and all its assets both tangible and intangible of every nature and wherever situated.

TO HAVE AND TO HOLD the same to the said Thomson Electric Welding Company of Massachusetts and its successors and assigns, to their own use and behoof forever.

And the said Thomson Electric Welding Company of Maine, does hereby constitute and appoint said Thomson Electric Welding

Company of Massachusetts its true and lawful attorney in the name and behalf of said Thomson Electric Welding Company of Maine, but to the use of said Thomson Electric Welding Company of Massachusetts to sign, seal, execute, acknowledge and deliver any and all instruments in writing necessary or convenient for the more effectual carrying out of the purposes and terms of this conveyance and transfer. It is understood and agreed, and is a part of the consideration of this conveyance, that said Thomson Electric Welding Company of Massachusetts shall assume and pay all legal debts and obligations of said Thomson Electric Welding Company of Maine now existing, and shall hold said Thomson Electric Welding Company of Maine harmless therefrom.

IN WITNESS WHEREOF the said Thomson Electric Welding Company of Maine has caused its corporate seal to be hereto affixed and this instrument to be executed, acknowledged and delivered in its name and behalf by Benjamin F. Spinney, its President, and William H. Hodges, its Treasurer, hereunto duly authorized, this eleventh day of March A. D. 1910.

THOMSON ELECTRIC
WELDING COMPANY

WHEREAS, the THOMSON ELECTRIC WELDING COMPANY, a corporation duly organized and existing under the laws of the State of Massachusetts and having an office at Lynn, in the said State, is desirous of acquiring the entire right, title and interest in and to the said inventions, Letters Patent, applications for patent and Letters Patent to be issued on the same in and for the United States and all other countries:

NOW, THEREFORE, To All Whom It May Concern:

Be it known that for and in consideration of the sum of One (1) Dollar to the THOMSON ELECTRIC WELDING COMPANY of Maine in hand paid by the THOMSON ELECTRIC WELDING COMPANY of Massachusetts and other good and valuable consideration, the receipt of which is hereby acknowledged, the said THOMSON ELECTRIC WELDING COMPANY of Maine has sold, assigned, transferred and set over and by these presents does sell, assign, transfer and set over unto the said THOMSON ELECTRIC WELDING COMPANY, of Massachusetts, its successors and assigns, the entire right, title and interest in and to the said in-

ventions, Letters Patent, applications for patent and Letters Patent to be issued for the same in

— 5 —

and for the United States and all other countries, together with the right, to be exercised in its own name and for its own use, to sue and recover for past infringement of said Letters Patent, the said inventions and Letters Patent issued and to be issued for the same, together with any reissue or reissues or extension or extensions of said Letters Patent, to be held and enjoyed by the said THOMSON ELECTRIC WELDING COMPANY of Massachusetts, its successors assigns, or other legal representatives, for its own use and behoof and for the use of its successors, assigns, or other legal representatives, to the end of the term or terms for which said Letters Patent are or may be granted, reissued or extended, as fully and entirely as the same would have been held and enjoyed by the said THOMSON ELECTRIC WELDING COMPANY of Maine, had this assignment and sale not been made.

And the said THOMSON ELECTRIC WELDING COMPANY of Maine hereby authorizes and requests the Commissioner of Patents to issue the Letters Patent for the inventions set forth in the above applications to the THOMSON ELECTRIC WELDING COMPANY of Massachusetts, as the sole owner thereof.

IN WITNESS WHEREOF the said THOMSON ELECTRIC WELDING COMPANY of Maine has caused its corporate seal to be hereto affixed and this instrument to be executed, acknowledged and delivered in its name and behalf this 18th day of April, 1910, by Benjamin F. Spinney, its President, and William H. Hodges, its Treasurer, hereunto duly authorized by the unanimous vote of the stockholders of said COMPANY, a copy of which vote is hereto annexed.

ASSIGNMENT

WHEREAS the THOMSON ELECTRIC WELDING COMPANY, a corporation duly organized and existing under the laws of the Commonwealth of Massachusetts, and, having an office in the City of Lynn, Massachusetts, did, by virtue of certain assignments duly executed and delivered and recorded in the United States Patent Office, acquire the entire right, title and interest in and to certain inventions set forth in Letters Patent of the United States and in and to the Letters Patent issued upon the same, said Letters Patent being entitled, numbered and dated as follows:

Uniting the Component Parts of Composite Sheet Metal Structures, No. 928,701, July 20, 1909;

Electric Welding of Sheet Metal No. 973,586, Oct. 25, 1910;

Sheave Welder, No. 985,838, Mar. 7, 1911;

Composite Sheet Metal, No. 1,020,056, Mar. 12, 1912;

Method of Joining Metal, No. 1,040,418, Oct. 8, 1912;

Electric Welding, No. 1,046,066, Dec. 3, 1912;

Electric Metal Working Apparatus, No. 1,074,383, Sept. 30, 1913;

Electrical Welding of Sheet Metal, No. 1,078,225, Nov. 11, 1913;

Electric Seam Welding, No. 1,083,956, Jan. 13, 1914;

Spot Welding Machine, No. 1,084,673, Jan. 20, 1914;

Spot Welding Thin Sheets, No. 1,085,769, Feb. 3, 1914;

Spot Welding, No. 1,097,895, May 26, 1914;

Spot Welding Machine, No. 1,122,665, Dec. 29, 1914;

Method of Electric Seam Welding, No. 1,123,624, Jan. 5, 1915

Electric Welding, No. 1,143,220, June 15, 1915;

Electric Metal Working Apparatus No. 1,174,446; Mar. 7, 1916; and

WHEREAS the said THOMSON ELECTRIC WELDING COMPANY, did by virtue of a certain assignment duly executed and delivered and recorded in the United States Patent Office, also acquire the entire right, title and interest in and to the invention relating to Combination Spot and Butt Welder set forth in a certain application for Letters Patent of the United States filed in the United States Patent Office on the 4th day of August, 1916, Serial Number 113,055; and

WHEREAS the THOMSON SPOT WELDER COMPANY, (formerly Electric Welder Company) a corporation duly organized and existing under the laws of the Commonwealth of Massachusetts and having an office in the City of Boston, State of Massachusetts is desirous of acquiring the entire right, title and interest in and to the said inventions, Letters Patent, application for patent and the Letters Patent to be issued on the same in and for the United States;

NOW THEREFORE, To All Whom It May Concern:

Be it known that for and in consideration of the sum of One Dollar ($1.00) to the THOMSON ELECTRIC WELDING COMPANY in hand paid by the THOMSON SPOT WELDER COMPANY and other good and valuable consideration, receipt of which is hereby

acknowledged, the said THOMSON ELECTRIC WELDING COMPANY has sold, assigned transferred and set over and by these presents does sell, assign

transfer and set over unto the said THOMSON SPOT WELDER COMPANY, its successors and assigns, the entire right, title and interest in and to the said inventions, Letters Patent, application for patent and Letters Patent to be issued for the same in and for the United States, together with any and all rights of action, claims and demands whatsoever of the said THOMSON ELECTRIC WELDING COMPANY either at law or in equity, for damages or profits or both, arising from past infringement of said Letters Patent, with the full right and power in its own name to sue for and collect the same for its own use and benefit, the said inventions and Letters Patent issued and to be issued for the same, together with any reissue or reissues or extension or extensions of said Letters Patent, to be held and enjoyed by the said THOMSON SPOT WELDER COMPANY, its successors, assigns or other legal representatives, for its own use and benefit and for the use of its successors, assigns or other legal representatives, to the end of the term or terms for which said Letters Patent are or may be granted, reissued or extended as fully and entirely as the same would have been held and enjoyed by the THOMSON ELECTRIC WELDING COMPANY had this assignment and sale not been made.

And the said THOMSON ELECTRIC WELDING COMPANY, hereby authorizes and requests the Commissioner of Patents to issue the Letters Patent for the invention set forth in the above application to the THOMSON SPOT WELDER COMPANY as the sole owner thereof.

IN WITNESS WHEREOF the said THOMSON ELECTRIC WELDING COMPANY has set its hand and seal this 14th day of February, 1917

Defendant's Exhibit No. 44.

WHEREAS, SEBASTIAN Z. de FERRANTI, of Grindleford Bridge, Sheffield, England, is the inventor of certain new and useful improvements in ELECTRIC WELDING, which invention is set forth and described in an application for Letters Patent of the United States, filed by said de FERRANTI in the United States Patent Office on the 29th day of December, 1911, Serial No. 668,464, said application being a division of an application for Letters Patent of the United States filed by said de FERRANTI in the United States Patent Office May 14th, 1904, Serial No. 208,034; and

WHEREAS, said de FERRANTI'S application Serial No. 668,464 is at present involved in Interference No. 36,709 in the United States Patent Office with Letters Patent of the United States for Electric Welding, No. 1,046,066, issued to Johann Harmatta December 3, 1912, and said de FERRANTI is entitled to priority of invention of the subject-matter of his said application under the provisions of the International Convention for the Protection of Industrial Property and of the Statutes of the United States as of May 25th, 1903, on which day he filed application for Letters Patent of Great Britain No. 11,921 of 1903 setting forth said invention; and

WHEREAS, HENRY C. MILLIGAN, TRUSTEE, of Canton, Ohio, is the owner by mesne assignments of said de FERRANTI application Serial No. 668,464, and of the invention therein set forth, and of the Letters Patent of the United States to issue thereon, and of all other rights in, to and under the same; and

WHEREAS, FORD MOTOR COMPANY, a corporation organized and existing under the laws of the State of Michigan, is desirous of acquiring a license under and interest in said de FERRANTI invention and application, and in, to and under any Letters Patent of the United States which may be granted therefor;

NOW, THEREFORE, in consideration of one dollar to said HENRY C. MILLIGAN, TRUSTEE, in hand paid by said FORD MOTOR COMPANY, and of other good and valuable considerations from said COMPANY to said MILLIGAN, TRUSTEE, moving, the receipt of which is hereby acknowledged, said HENRY C. MILLIGAN, TRUSTEE, hereby gives and grants unto said FORD MOTOR COMPANY the right and license to use said invention, excepting for the manufacture of spinning machinery and turbines, under said application Serial No. 668,464, and under any Letters Patent of the United States which may be granted thereon, such right and license to relate back to, and to be deemed to be in full force and effect since May 25, 1903, the date of priority of invention to which said de FERRANTI is entitled, and to continue in force to the expiration of any Letters Patent of the United States which may be granted on said de FERRANTI application Serial No. 668,464, meaning and intending hereby to confer upon

said FORD MOTOR COMPANY a right and license under said invention, application and Letters Patent to issue thereon, and right of priority thereunder coextensive in time with that enjoyed by said de FERRANTI and those deriving title or interest from and under him.

SIGNED, sealed and delivered at Canton, Ohio, this 30th day of November, 1917.

THOMSON ELECTRIC WELDING COMPANY AND UNIVERSAL ELECTRIC WELDING COMPANY

vs.

BARNEY & BERRY, INC.

INTERLOCUTORY DECREE.

July 17, 1916.

DODGE, J. This cause came on to be further heard upon the pleadings and proofs and upon the Mandate of the Circuit Court of Appeals for the First Circuit, and counsel for the respective parties having been heard, now, upon consideration thereof it is hereby ordered, adjudged and decreed that the Letters Patent of the United States referred to in the complainant's bill granted to the Thomson Electric Welding Company, as assignee of Johann Harmatta, No. 1,046,066, dated December 3, 1912, are good and valid; that said Johann Harmatta was the original and first inventor of the improvements described in said Letters Patent; that the complainant, the Thomson Electric Welding Company, is the true and lawful owner of said Letters Patent; that the complainant, the Universal Electric Welding Company, is a licensee under said Letters Patent; and that the defendant, Barney & Berry, Inc., has infringed claims 3, 4, 5, 6, 8, 9, 11, 12 17, 18 19 and 21 of said Letters Patent and upon the exclusive rights of the complainants under the same.

It is further ordered adjudged and decreed, that the complainants recover of the defendant the gains and profits which said defendant has derived, received or made by reason of its infringement of said claims of said Letters Patent, and that said complainants also recover any and all damages which they have sustained by reason of said infringement of said claims by the defendant; and this cause is hereby referred to
as a master of this court, to take and state an account of such gains and profits, and to assess such damages and to report thereon with all convenient speed. And the officers and employees of the defendant are hereby directed and required to attend before said master from time to time as required, and to produce before him such books, papers and documents as relate to the matters at issue, and to submit to such oral examination as the master may require.

It is further ordered, adjudged and decreed, that a perpetual in-

junction be issued out of and under the seal of this court against the said defendant, Barney & Berry, Inc., strictly enjoining and restraining it, its clerks, attorneys, agents, servants and workmen from directly or indirectly infringing said Letters Patent, and from practising the process of electric welding containing or embodying the invention described and patented in said Letters Patent and referred to in the claims thereof numbered 3, 4, 5, 6, 8, 9, 11 and 12, and from directly or indirectly making, constructing, using or selling metal articles containing or embodying the invention described and patented in said Letters Patent, and referred to in the claims thereof numbered 17, 18, 19 and 21.

It is further ordered, adjudged and decreed, that the complainants recover of the defendant their costs of suit to be taxed.

By the Court.

vs.

NATIONAL ENAMELING & STAMPING COMPANY, DEFENDANT.

IN EQUITY.

JOHN A SHIELDS,
Clerk Circuit Court U. S. Southern District of N. Y.

You will please issue a Subpoena to the defendant in the above-entitled action, returnable on the first Monday of January, 1911.

HENRY C. TOWNSEND,
Solicitor for Complainant.

New York, Nov. 17, 1910.

(Endorsed) U. S. Circuit Court, Southern District New York, Filed Nov. 17, 1910, John A. Shields, Clerk.

THE PRESIDENT OF THE UNITED STATES OF AMERICA
To
NATIONAL ENAMELING & STAMPING COMPANY, GREETING:

YOU ARE HEREBY COMMANDED that you personally appear before the Judges of the Circuit Court of the United States of America, for the Southern District of New York, in the Second Circuit, in Equity, on the first Monday of January, A. D. 1911 wherever the said Court shall then be, to answer a bill of complaint exhibited against you in the said Court by THOMSON ELECTRIC WELDING COMPANY and UNIVERSAL ELECTRIC WELDING COMPANY, and do further and receive what the said Court shall have considered in that behalf. And this you are not to omit under the penalty on you of Two Hundred and Fifty Dollars.

WITNESS, The Honorable JOHN M. HARLAN, Associate Justice of the Supreme Court of the United States, at the Borough of Manhattan, in the City of New York, on the 17th day of November, in the year of our Lord one thousand nine hundred and ten, and of the Independence of the United States of America, the one hundred and thirty-fifth.

JOHN A. SHIELDS, *Clerk.*

HENRY C. TOWNSEND,
Solicitor for Complainant,
149 Broadway.

The Defendant is required to enter appearance in the above cause, in the Clerk's Office of this Court, on or before the first Monday of January, 1911, or the bill will be taken *pro confesso* against it.

J. A. S., *Clerk.*

I HEREBY CERTIFY, That on the 17th day of November, 1910, at the City of New York, in my district, I served the within Subpoena in Equity upon the within-named Defendant National Enameling and Stamping Company by exhibiting to Adolph M. Steinhardt as Treasurer of said Company at No. 81 Fulton Street, N. Y. City, the within original, and at the same time leaving with him a copy thereof.

WM. HENKEL,
United States Marshal, Southern District of New York.

IN THE CIRCUIT COURT OF THE UNITED STATES, FOR THE SOUTHERN DISTRICT OF NEW YORK.

THOMSON ELECTRIC WELDING COMPANY and UNIVERSAL ELECTRIC WELDING COMPANY, PLAINTIFFS,

vs.

NATIONAL ENAMELING & STAMPING COMPANY, DEFENDANT.

IN EQUITY.

BILL OF COMPLAINT.

TO THE HONORABLE JUDGES OF THE CIRCUIT COURT OF THE UNITED STATES FOR THE SOUTHERN DISTRICT OF NEW YORK:

1. The Thomson Electric Welding Company, a corporation duly organized and existing under the laws of the State of Massachusetts and having a principal place of business at Lynn, in the State of Massachusetts, and the Universal Electric Welding Company, a corporation duly organized and existing under the laws of the State of New York and having a principal place of business in the Borough of Queens, in the City of New York, State of New York, bring this, their bill of complaint, against the National Enameling & Stamping Company, a corporation organized and existing under the laws of the State of New Jersey, having a regular and established place of business, and having committed acts of infringe-

ment as hereinafter complained of, within the Southern District of New York, and thereupon your orators complain and say:

2. That, as your orators are informed and believe and accordingly aver, Adolph F. Rietzel, being a citizen of the United States and a resident of Lynn, in the County of Essex, and State of Massachusetts, was prior to the twenty-fourth day of February, nineteen hundred and five, the original and first inventor of certain new and useful improvements in Uniting the Component parts of Sheet Metal Structures, since commonly known in the art as Electric Spot or Point Welding, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof or more than two years prior to his hereinafter recited application for patent therefor, and not in public use or on sale in this country for more than two years before his said application for Letters Patent, and not patented or caused to be patented by him or his legal representatives or assigns in any foreign country upon any application for foreign patent filed more than one year prior to the filing of his hereinafter recited application for patent for said invention, and not abandoned prior to said application; and that, being said original and first inventor the said Adolph F. Rietzel on or before the twenty-fourth day of February, 1905, made application in due form of law to the Commissioner of Patents of the United States for Letters Patent for his said invention and duly swore to the specification thereof, and by valid assignment assigned to the Thomson Electric Welding Company a corporation duly organized under the laws of the State of Maine, his said application and invention therein set forth and any Letters Patent that might be granted for said invention, and requested the Commissioner of Patents to issue to said Thomson Electric Welding Company of Maine as his assignee any Letters Patent which might be granted on his said application; whereupon such proceedings were had that on the twentieth day of July, 1909, Letters Patent of the United States No. 929,701 were granted to the said Thomson Electric Welding Company of Maine in conformity with the requirements of the statutes in such case made and provided, which said Letters Patent in their terms granted to said Thomson Electric Welding Company of Maine, its successors and assigns, for the term of seventeen years from said last mentioned day, the exclusive right to make, use and vend the invention therein described and claimed, referring to the specifications for the particulars thereof, and your orators bring here into Court a duly authenticated copy of said Letters Patent and pray that the same may be taken as a part of this bill.

3. And your orators further show that the Thomson Electric Welding Company of Maine to whose rights your orator, the Thomson Electric Welding Company of Massachusetts succeeded, as hereinafter set forth, entered into certain agreements with your orator, the Universal Electric Welding Company, dated respectively

the 26th day of February, 1909, and the 20th day of July, 1909, which agreements ever since the issuance of said patent and up to the beginning of this action have been continuously in full force and effect, whereby your orator, the Universal Electric Welding Company, acquired the exclusive right to use the invention covered by the aforesaid Letters Patent in connection with machines built by said Thomson Electric Welding Company of Maine or with its permission, and leased to your orator, the Universal Electric Welding Company, upon a continuing fixed annual rental or royalty, to be paid to the said Thomson Electric Welding Company of Maine, its successors and assigns, together with the right to sublease and let said machines, subject to the conditions and covenants of said agreements, as in and by said agreements here in Court to be produced will more fully appear.

4. And your orators further show that by valid mesne assignments duly recorded in the office of the Commissioner of Patents of the United States, all the right, title and interest of said Thomson Electric Welding Company of Maine in and to said Letters Patent and in and to the invention secured thereby, including the right to sue for and recover all damages and profits that might be due to the Thomson Electric Welding Company of Maine for the infringement of the said Letters Patent prior to the aforesaid assignments, subject to the rights of your orator the Universal Electric Welding Company, as hereinbefore set forth, became vested in your orator the Thomson Electric Welding Company of Massachusetts, and your orator then became and ever since have been and now are the owners of said Letters Patent and as such entitled to and possessed of the full and exclusive right and liberty of making, constructing, using and vending to others to be used, the aforesaid invention within and throughout the United States and the Territories thereof, and entitled to collect and hold to their own use all damages and profits that are recoverable for past infringement of said Letters Patent since the date thereof, as in and by said assignments, or duly certified copies thereof here in Court to be produced will more fully appear.

5. Your orators further show that the art of electric spot or point welding covered by the claims of the aforesaid Letters Patent is of great value and importance in the art of manufacturing metal articles and particularly articles of sheet metal and that your orators have expended large sums of money in exploiting said invention and bringing the same to the notice of various manufacturing concerns and have been paid large sums of money for the right to use the invention of spot or point welding set forth in and covered by the claims of the aforesaid Letters Patent and continue to receive and expect to receive further large sums of money for said rights and that the wrongful acts of the defendant herein complained of will have the effect of encouraging others to violate your orators' exclusive rights and to refuse to pay the further sums of money due your orators for the grant of the rights to use said patented invention.

6. And your orators further show that the defendant was duly notified of the rights of your orators and of the Thomson Electric Welding Company of Maine in the premises but that after such notice, as your orators are informed and believe and accordingly aver, the defendant although well knowing the premises and exclusive rights of your orators and of the Thomson Electric Welding Company of Maine as aforesaid, in violation of said rights, and with the intent of depriving your orators and the Thomson Electric Welding Company of Maine of the benefit and advantages which would otherwise accrue to your orators from the possession of the exclusive rights conferred by the above mentioned Letters Patent, and without the license and consent of your orators or of the Thomson Electric Welding Company of Maine and against their will, and in infringement of said Letters Patent have been since the 20th day of July, 1909, within the Southern District of New York and at its factory in New York in said District, and elsewhere in the United States, using the art or method of electric point or spot welding set forth and claimed in the aforesaid Letters Patent and have made and sold metal plates, articles and metal work as set forth and claimed in said Letters Patent and that the defendant threatens to continue to so violate the exclusive rights conferred by the said Letters Patent and to install additional machines for practicing the said art or method and for manufacturing the metal work and articles set forth and claimed in said Letters Patent.

7. To the end therefore, that the defendant may, if it can, show why your orators should not have the relief herein prayed, and may, according to the best of its knowledge, information, remembrance and belief, full, true, and perfect answer make (but not under oath, an answer under oath being hereby expressly waived) to all and singular the matters herein stated and charged, as fully and particularly as if the same were here repeated and the defendant especially interrogated as to each and every of such matters; and that by a decree of this Court the defendant may be compelled to account for and pay over to your orators all damages which your orators and the Thomson Electric Welding Company of Maine have sustained, or shall sustain, on account of the defendant's infringement of said Letters Patent, together with all gains and profits resulting to the defendant from said infringement, and that the defendant, its officers, clerks, attorneys, agents, servants, and workmen, may be restrained, permanently and during the pendency of this suit, by an injunction, from using or practicing the method of uniting the component parts of composite sheet-metal structures as described and claimed in said Letters Patent and from using or causing to be used, machines or apparatus operating according to said method and from making, using and selling any metal plates or articles as described and claimed in said Letters Patent; and that it may be decreed to pay the costs of this suit and that your orators may have such other and further relief as the nature of this case may require, and to this Court may seem meet; may it please your

Honors to grant unto your orators not only a writ or writs of injunction conformable to the prayer of this bill but also a writ of subpoena ad respondendum, issuing out of and under the seal of this Honorable Court, directed to the said National Enameling and Stamping Company, commanding it to appear and make answer to this bill of complaint, and to perform and abide by such order and decree herein as to this Court may seem required by the principles of equity and good conscience.

And your Orators as in duty bound will ever pray.

(Seal) THOMSON ELECTRIC WELDING COMPANY,
By WILLIAM H. HODGES, *Secretary.*
UNIVERSAL ELECTRIC WELDING CO.,

IN THE CIRCUIT COURT OF THE UNITED STATES,

FOR THE SOUTHERN DISTRICT OF NEW YORK.

THOMSON ELECTRIC WELDING COMPANY and UNIVERSAL ELECTRIC WELDING COMPANY, PLAINTIFFS,

vs.

NATIONAL ENAMELING & STAMPING COMPANY, DEFENDANT.

IN EQUITY 7-2.

DEFENDANT'S ANSWER.

TO THE HONORABLE JUDGES OF THE CIRCUIT COURT OF THE UNITED STATES, FOR THE SOUTHERN DISTRICT OF NEW YORK:

The Answer of the National Enameling and Stamping Company a Corporation duly organized and existing under the laws of the

State of New Jersey and having a principal place of business at No. 81 and 83 Fulton Street in the City of New York, in the State of New York, defendant herein, to the Bill of Complaint of the Thomson Electric Welding Company and the Universal Electric Welding Company, complainants herein.

This defendant, now and at all times hereafter saving and reserving to itself all and all manner of benefit and advantage of exception that can or may be had or taken to the manifold errors, uncertainties, imperfections and insufficiencies in the said bill of complaint contained, for answer thereto or to so much thereof as it is advised to be material or necessary for it to make answer unto, answering says:

FIRST: This defendant is not informed, save by the Bill of Complaint, whether the complainant, The Thomson Electric Welding Company is a corporation or is organized and exists under the Laws of the State of Massachusetts and therefore denies the same and leaves the complainants to make such proof thereof as they may be advised is material.

This defendant is not informed, save by the Bill of Complaint, whether the Complainant, The Universal Electric Welding Company, is a corporation duly organized and existing under the laws of the State of New York, and therefore denies the same and leaves the complainants to make such proof thereof as they may be advised is material.

This defendant admits that the National Enameling and Stamping Co. is a corporation duly organized under the laws of the State of New Jersey, and has a regular and established place of business in the City of New York and State of New York.

SECOND: This defendant, on information and belief, denies that Adolph F. Rietzel was or is the true, or the original, or the first inventor of a certain new and useful improvement in Uniting the Component Parts of Composite Sheet-Metal Structures or any new and useful improvements therein, as described in the specifications of the Letters Patent No. 928,701 and issued on the 20th day of July, 1909 to the Thomson Electric Welding Company of Lynn, Massachusetts, a corporation of Maine, as the assignee of the said Adolph F. Rietzel as alleged in said Bill of Complaint; denies that said Rietzel was the original and first inventor of the alleged improvement in Uniting the Component Parts of Sheet-Metal Structures, alleged to be since commonly known as Electric Spot or Point Welding; denies that the said invention was not known or used by others in this country before his (said Rietzel's) alleged invention; denies that it was not patented or described in any printed publication before his alleged invention or discovery, or more than two years prior to the filing in the United States Patent Office of his application for patent therefor; denies that the said method of electric spot welding was not in public use or machines therefor on sale in this country for more than two years before the date of his said application for said United States Let-

ters Patent; denies that said invention was not patented or caused to be patented by him or his legal representatives or assigns in any foreign country upon any application for patent filed more than one year prior to the filing on February 24, 1905 of his said application for United States Letters Patent here in suit. Whether said Rietzel made application in due form of law to the Commissioner of Patents of the United States for said alleged invention, or whether said Rietzel made or executed valid assignments of said invention or patent to the said Thomson Electric Welding Company of Maine, this defendant has no knowledge, information or belief and therefore leave the complainants to make proof thereof as they may be advised is material. But this defendant on information and belief denies that any title in and to said invention or Letters Patent became vested in said Company.

THIRD: This defendant admits that certain letters patent of the United States No. 928,701 bearing date July 20th, 1909 for an alleged improvement in Uniting the Component parts of Composite Sheet-Metal Structures were issued to Adolph F. Rietzel, assignor to Thomson Electric Welding Company, of Lynn, Massachusetts, a corporation of Maine, but it denies that said letters patent secured to said Rietzel or to said Thomson Electric Welding Company of Maine or the Complainants, the exclusive right, or any right, to make, use and vend the said alleged invention.

FOURTH: This defendant is not informed save by the Bill of Complaint as to whether the several instruments in writing set forth in the said Bill of Complaint as assigning and transferring to these complainants the rights and interests alleged in the Bill of Complaint as arising out of the said letters patent No. 928,701 were ever made, executed or recorded in the Patent Office of the United States as alleged, and therefore on information and belief denies the same and leaves the complainants to make such proof thereof as they may be advised is material.

FIFTH: This defendant further answering says it has no knowledge, information or belief that the said patent No. 928,701 is for the art of electric spot or point welding, or that spot or point welding is covered by the claims of the aforesaid Letters Patent or that it is of great value and importance, and therefore denies the same and leaves the complainants to make such proof thereof as they may be advised.

SIXTH: This defendant is not informed save by the Bill of Complaint whether or not Complainants have expended large sums of money in exploiting the invention purporting to be disclosed by said Letters Patent, or whether or not Complainants have spent large sums in bringing the said invention or patent to the notice of the various manufacturing concerns, and therefore deny the same, and leave the complainants to make such proof thereof as they may be advised is material;

Whether or not complainants have been paid large sums of money for the privilege of using the alleged invention of spot or

point welding set forth in and covered by the claims of said patent defendants do not know and are not informed save by said Bill of Complaint, and on information and belief therefore deny and require the Complainants to prove.

Whether or not complainants have received large sums of money for rights to use said invention, or expect to receive further large sums for such rights, defendants do not know and have not heard save as set forth in the Bill of Complaint, and therefore defendants deny the same and leave to Complainants to make proof.

SEVENTH: This defendant further answering denies that it has since the 20th day of July, 1909 used the art of electric point or spot welding set forth and claimed in the aforesaid Letters Patent No. 928,701, and denies that it has made, used or sold articles of sheet-metal that are an infringement of any claim of said patent.

This defendant admits that it has practiced and used a method of electrically welding sheet-metal articles, and was doing so for many years prior to the issue of said Letters Patent on the 20th day of July, 1909. Defendant avers that it is not indebted in the slightest degree to any disclosure in said patent of Complainants for the knowledge that defendant possesses of the art and method of electrically welding sheet-metal articles as the same has been practiced and used by the defendant long prior to July 20th, 1909, the date of said letters patent No. 928,701, and long prior to any knowledge or any information defendant has of said letters patent or of said Rietzel the alleged inventor thereof.

EIGHTH: This defendant further answering on information and belief, avers that the alleged improvements or inventions set forth in said patent 928,701 of Complainants are not new and useful, and their production does not and did not amount to invention in view of the state of the art existing prior to the date of the application of said Rietzel for his said letters patent.

NINTH: This defendant further answering, on information and belief avers that the said Adolph F. Rietzel for the purpose of deceiving the public made the descriptions and specifications filed by him in the Patent Office as a part of his application for said letters patent No. 928,701, to contain less than the whole truth relative to his alleged invention or discovery, and that the said Letters Patent No. 928,701 are therefore invalid and void.

TENTH: This defendant further answering says that the alleged invention described in said letters patent No. 928,701 was not, at the date of the application for said letters patent, a proper subject of letters patent of the United States, and did not involve, constitute or amount to invention or discovery but was in fact the mere adoption of the inventions or discoveries of others, made, used, patented and described in printed publications long prior to the application for said letters patent, and prior to the said alleged invention of said Adolph F. Rietzel.

ELEVENTH: This defendant further answering, on informa-

tion and belief, denies that the said Adolph F. Rietzel was the original or first inventor or discoverer of the improvements described and claimed in said Letters Patent No. 928,701 or of any material or substantial parts thereof and that the said alleged inventions, and improvements had been prior to the said alleged invention and discovery thereof by the said Adolph F. Rietzel, patented, described and shown in the following United States Letters Patent and had been known and used by the patentees thereof as follows, to wit:—

And other United States and Foreign Letters Patent at present to the Defendant unknown, which Defendant prays leave, when discovered, to insert herein by amendment.

TWELFTH: This defendant further answering, on information and belief, avers that the said Adolph F. Rietzel was not the original or first inventor or discoverer of the inventions of Letters Patent No. 928,701 or of any material or substantial part thereof, but that the same and all material or substantial parts thereof was known and in public use and the products or articles claimed therein were on sale in this country prior to the date of said Rietzel's application for said Letters Patent No. 928,701 by the following named persons whose places of residence are given together with the places where such public use or sale occurred:

Edwin F. Angell, of Somerville, Mass., at Somerville, Mass. and elsewhere in the United States;

George D. Burton, of Somerville, Mass., at Somerville, Mass. and elsewhere in the United States.

Robert P. Brown, of New York, N. Y. at New York, N. Y. and elsewhere in the United States;

Hermann G. Blevin of Newcastle, Penna., at Newcastle, Penna. and elsewhere in the United States;

Charles L. Coffin, of Detroit, Mich., at Detroit, Mich., and elsewhere in the United States.

Eugene Diven, of Elmira, N. Y., at Elmira, N. Y., and elsewhere in the United States;

Thomas A. Edison, of Orange, N. J., at Orange, N. J., and elsewhere in the United States;

Richard Eyre, of Johnstown, Pa., at Johnstown, Pa., and elsewhere in the United States;

Rudolph M. Hunter, of Philadelphia, Pa., at Philadelphia, Pa., and elsewhere in the United States;

Henry F. A. Kleinschmdit, of Johnstown, Pa., at Johnstown, Pa., and elsewhere in the United States;

Lorain Steel Co., of Lorain, Ohio, at Lorain, Ohio, and elsewhere in the United States;

Arthur J. Moxham, of Johnstown, Pa., at Johnstown, Pa., and elsewhere in the United States;

Franklin E. Morse, of New York, N. Y., at New York, N. Y., and elsewhere in the United States;

David W. Payne, of Elmira, N. Y. at Elmira, N. Y., and elsewhere in the United States.

John C. Perry, of Clinton, Mass., at Clinton, Mass., and elsewhere in the United States;

Russell Robb, of Boston, Mass., at Boston, Mass., and elsewhere in the United States.

Elias E. Ries, of Baltimore, Md., at Baltimore, Md., and elsewhere in the United States;

Elihu Thomson, of Lynn, Mass., at Lynn, Mass., and elsewhere in the United States;

Henry C. White, of Worcester, Mass., at Worcester, Mass., and elsewhere in the United States:

And by others at present to this defendant unknown, the names and addresses of whom and the places where the said uses and sale occurred the defendant, when discovered, prays leave to insert herein by amendment.

THIRTEENTH: This defendant further answering on information and belief avers that the methods claimed in said Letters Patent No. 928,701 are merely an adaptation of old and known methods to accomplish no novel result, and consist in the omission of a step or steps of said old and known methods with the omission in said claims of a statement of the purpose or result accomplished by said steps.

FOURTEENTH: This defendant further answering avers that the methods claimed in said Letters Patent of the United States No. 928,701 granted to said Rietzel are fully disclosed in the prior Letters Patent of the United States No. 690,958 issued to Rudolph M. Hunter, January 14, 1902 but are not claimed therein, said prior patent having been granted more than two years before said Rietzel filed his application for said patent No. 928,701, and that therefore the said methods were dedicated to the public by said Hunter, and could not in law be claimed by said Rietzel.

FIFTEENTH: This defendant further answering on information and belief alleges that the said Letters Patent No. 928,701 are invalid by reason of the fact that the claims thereof are too broad in view of the state of the prior art at the time that the application for such Letters Patent was filed, and also by reason of the fact that said claims were so greatly expanded beyond what they were when the Rietzel application was originally filed, as to describe a different invention.

SIXTEENTH: This defendant further answering denies all and all manner of wrongdoing wherewith it is charged in the bill of complaint, asserts that the said patent 928,701 has never been adjudicated in the Courts, and denies the right of Complaiannts to an injunction or an accounting, or any other relief prayed for in said Bill or otherwise, and defendant prays the same advantage for this answer as if it had pleaded the several matters and things aforesaid, as if for the reasons thereof it had demurred to the said bill of complaint where demurrer would have been proper, and the same benefit thereof as if it had specially pleaded to the bill where a special plea would have been proper; and it submits to this

Honorable Court that the premises considered the Complainants have no right to any further answer to said bill or any part thereof than is hereinbefore contained, and no right to any discovery, injunction, accounting, or any relief prayed for in said bill, and this defendant prays to be hence dismissed with its reasonable costs and charges in this behalf most wrongfully sustained.

REPLICATION.

The replication of the above-named plaintiffs to the answer of the above-named defendant.

These replicants, saving and reserving to themselves all and all manner of advantage of exception which may be had and taken to the manifold errors, uncertainties, and insufficiencies of the answer of said defendant, for replication thereunto say that they do and will ever maintain and prove their said bill to be true, certain, and sufficient in the law to be answered unto by said defendant, and that the answer of said defendant is very uncertain, evasive, insufficient in the law to be repied unto by these replicants; without this, that any other matter or thing in the said answer contained material or effectual in the law to be replied unto, confessed, or avoided, traversed or denied, is true; all which matters and things these replicants are ready to aver, maintain, and prove as this Honorable Court shall direct, and humbly as in and by their said bill they have already prayed.

HENRY C. TOWNSEND,

Defendant's Exhibit No. 48.

IN THE DISTRICT COURT OF THE UNITED STATES FOR THE EASTERN DISTRICT OF NEW YORK.

THOMSON ELECTRIC WELDING COMPANY and UNIVERSAL ELECTRIC WELDING COMPANY, PLAINTIFFS,

vs.

UNITED STATES METAL PRODUCTS COMPANY, DEFENDANT.

IN EQUITY, No. 11.

BILL OF COMPLAINT.

To the Judges of the District Court of the United States for the Eastern District of New York:

1. The Thomson Electric Welding Company, a corporation duly organized and existing under the laws of the State of Massachusetts and having a principal place of business at Lynn, in the State of Massachusetts, and the Universal Electric Welding Company, a corporation duly organized and existing under the laws of the State of New York and having a principal place of business in the Borough of Queens, in the City of New York, State of New York, bring this, their bill of complaint, against the United States Metal Products Company, a corporation organized and existing under the laws of the State of Massachusetts and having a regular and established place of business, and having committed acts of infringement, as hereinafter complained of, at College Point, within the Eastern District of New York, and thereupon your orators complain and say:

2. That, as your orators are informed and believe and accordingly aver, Adolph F. Rietzel, being a citizen of the United States and a resident of Lynn, in the County of Essex and State of Massachusetts, and prior to the twenty-fourth day of February, Nineteen Hundred and Five, was the inventor of certain new and useful improvements in Uniting the Component Parts of Metal Structures, since commonly known in the art as Electric Spot or Point Welding, and not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof or more than two years prior to his hereinafter recited application for patent therefor, and not in public use or on sale in this country for more than two years before his said application for Letters Patent, and not patented or caused to be patented by him or his legal representatives or assigns in any foreign country, upon any application for foreign patent filed more than one year prior to the filing of his hereinafter recited application for patent for said invention.

3. And your orators further show that after the filing of his

hereinafter recited application for Letters Patent and before the issuance of the Letters Patent, the said Adolph F. Rietzel, by an instrument in writing executed and delivered on or about the twenty-third day of March, Nineteen Hundred and Five, and recorded in the Transfers of Patents in the United States Patent Office on the twenty-second day of June, Nineteen Hundred and Five, in Liber H 72, p. 141, did sell, assign and transfer unto the Thomson Electric Welding Company, a corporation organized and existing under the laws of the State of Maine and having its principal office and place of business in the City of Lynn, State of Massachusetts, its successors and assigns, the whole right, title and interest in and to his aforesaid invention and application for patent therefor hereinafter recited and did authorize and request the Commissioner of Patents to issue the Letters Patent for said invention to the said Company as the sole owner thereof.

4. And your orators further show on information and belief that the said Adolph F. Rietzel made application according to law for Letters Patent of the United States for the aforesaid invention and that thereafter and after due proceedings had in all respects, and in pursuance of the aforesaid assignment, Letters Patent in due form of law for said invention were issued and delivered to the aforesaid Thomson Electric Welding Company, a corporation of Maine, as assignee of the said Adolph F. Rietzel, in the name of the United States of America under the seal of the Patent Office and signed by the Commissioner of Patents, granting to the said Thomson Electric Welding Company, a corporation of Maine, its successors and assigns, for the term of seventeen years from the twentieth day of July, 1909, the exclusive right to make, use and vend the said invention of Adolph F. Rietzel throughout the United States and the Territories thereof, as by said Letters Patent numbered 928,701, and dated July 20th, Nineteen Hundred and Nine, or a duly exemplified copy thereof, in Court to be produced, will more fully and at large appear.

5. And your orators further show that after the aforesaid assignment by Adolph F. Rietzel and prior to the issuance of the before-mentioned Letters Patent the Thomson Electric Welding Company of Maine to whose rights your orator, the Thomson Electric Welding Company of Massachusetts succeeded, as herein set forth, entered into a certain agreement with your orator, the Universal Electric Welding Company, which agreement, ever since the issuance of said patent and up the beginning of this action, has been continuously in full force and effect, whereby your orator, the Universal Electric Welding Company, acquired the exclusive right to use the invention covered by the aforesaid Letters Patent in connection with machines built by said Thomson Electric Welding Company of Maine or with its permission, and leased to your orator, the Universal Electric Welding Company, upon a continuing fixed annual rental or royalty, to be paid to the said Thomson Electric Welding Company of Maine, its successors and assigns,

together with the right to sub-lease and let said machines, subject to the conditions and covenants of said agreement.

6. And your orators further show that until the execution and delivery of the instruments in writing specified in the next succeeding paragraph numbered 7, of this bill, the said Thomson Electric Welding Company of Maine remained the sole owner of the entire legal right, title and interest in and to the aforesaid Letters Patent and of all the rights, interests, obligations and remedies belonging to it by virtue of the aforesaid agreement between it and your orator, the Universal Electric Welding Company.

7. Your orators further show that by two certain instruments in writing executed and delivered respectively on or about the 11th day of March, 1910, and the 18th day of April, 1910, and duly recorded respectively in the Transfers of Patents in the United States Patent Office, July 19th, 1910, Liber S 84, p. 292 and 294, and April 27th, 1910, in Liber J 84, p. 112, the Thomson Electric Welding Company of Maine did sell, assign, transfer and convey unto your orator, the Thomson Electric Welding Company of Massachusetts, all its property, both real and personal, and all its assets, both tangible and intangible, of every nature and wherever situated, including the entire right, title and interest in and to the aforesaid invention and Letters Patent and the right to sue and recover for past infringement of said Letters Patent, and that your orator, the Thomson Electric Welding Company of Massachusetts, has ever since and up to the beginning of this action been the owner of all the rights, titles and interests thereby conveyed in and to the aforesaid Letters Patent and rights of action and in and under the aforesaid contract between your orator, the Universal Electric Welding Company and the Thomson Electric Welding Company of Maine.

8. Your orators further show that the art of electric spot or point welding covered by the claims of the aforesaid Letters Patent is of great value and importance in the art of manufacturing metal articles and particularly articles of sheet metal and that your orators have expended large sums of money in exploiting said invention and bringing the same to the notice of various manufacturing concerns and have been paid large sums of money for the right to use the invention of spot or point welding set forth in and covered by the claims of the aforesaid Letters Patent and continue to receive and expect to receive further large sums of money for said rights and that the wrongful acts of the defendant herein complained of will have the effect of encouraging others to violate your orators' exclusive rights and to refuse to pay the further sums of money due your orators for the grant of the rights to use said patented invention.

9. And your orators further show that the defendant was duly notified of the rights of your orators in the premises but that after such notice, as your orators are informed and believe and accordingly aver, and well knowing the premises and exclusive rights of your orators as aforesaid, and in violation of said rights, and with the intent of depriving your orators of the benefit and advantages

which would otherwise accrue to your orators from the possession of the exclusive rights conferred by the above-mentioned Letters Patent, and without the license and consent of your orators and against their will, and in infringement of said Letters Patent within six years before the commencement of this suit, did, within the Eastern District of New York and at its factory in College Point in said District, use the art or method of electric point or spot welding set forth and claimed in the aforesaid Letters Patent and did make and sell metal plates, articles and metal work set forth and claimed in said Letters Patent and threatens to continue to so violate the exclusive rights conferred by the said Letters Patent and to install additional machines for practicing the said art or method and manufacturing the metal work and articles set forth and claimed in said Letters Patent, without the license and consent of your orators and against the will of your orators and in infringement of said Letters Patent.

10. And your orators further show, on information and belief, that the machine used in practicing the electric point or spot welding complained of and on which the metal plates, articles and metal work complained of are made, is specially designed, adapted and constructed for the purpose of such use, and was sold to the predecessors of the defendant, United States Metal Products Company, from whom your orators aver, on information and belief, the said defendant, United States Metal Products Company, obtained title by The Toledo Electric Welding Company, a corporation of Ohio, and that the said The Toledo Electric Welding Company is engaged in the business of selling and has already sold, within six years before the commencement of this suit, a large number of machines of substantially the same design and construction, to other persons, for the same use; and for as much as the said The Toledo Electric Welding Company is out of the jurisdiction of this Court and as your orators are informed and believe, has agreed to defend any suits for infringement of the aforesaid Letters Patent brought against any users of machines sold by it, and for as much as said Company is largely interested in the event of this suit, these Complainants hereby invite the said The Toledo Electric Welding Company to appear and be made a party-defendant in this suit and to defend the party named as defendant.

11. TO THE END THEREOF, that the defendant may, if it can, show why your orators should not have the relief herein prayed, and may, according to the best of its knoweldge, information, remembrance and belief, full, true, and perfect answer make (but not under oath, an answer under oath being hereby expressly waived) to all and singular the matters herein stated and charged, as fully and particularly as if the same were herein repeated and the defendant especially interrogated as to each and every of such matters; that by a decree of this Court the defendant may be compelled to account for and pay over to your orators all damages which your orators have sustained, or shall sustain, on account of the defendant's in-

fringement of said Letters Patent, together with all gains and profits resulting to the defendant from said infringement; that the defendant, its officers, clerks, attorneys, agents, servants, and workmen, may be restrained, permanently and during the pendency of this suit, by an injunction, from using or practicing the method of uniting the component parts of composite sheet metal structures as described and claimed in said Letters Patent and from using or causing to be used, machines or apparatus operating according to said method and from making, using and selling any metal plates or articles as described and claimed in said Letters Patent; that it may be decreed to pay the costs of this suit and that your orators may have such other and further relief as the nature of this case may require, and to this Court may seem just.

12. MAY IT PLEASE YOUR HONORS to grant to your orators not only a writ of injunction but also a writ of subpoena, issuing out of and under the seal of this Honorable Court, and directed to the said United States Metal Products Company, and commanding it to appear and make answer to this bill of complaint, and to perform and abide by such order and decree herein as to this Court shall seem just.

(Seal) *Notary Public, Queens Co.*

UNITED STATES DISTRICT COURT, FOR THE EASTERN DISTRICT OF NEW YORK.

THOMSON ELECTRIC WELDING COMPANY and UNIVERSAL ELECTRIC WELDINDG COMPANY, COMPLAINANTS,

vs.

UNITED STATES METAL PRODUCTS COMPANY, DEFENDANT.

IN EQUITY NO. 928,701—ON RIETZEL PATENT.

ANSWER.

To the Honorable the Judges of the United States District Court for the Eastern District of New York:

This defendant, now and at all times, saving and reserving unto itself all benefit and advantage of exception which can or may be had or taken to the manifold errors, uncertainties, imperfections, and insufficiencies of said bill of complaint for answer thereunto, or unto so much or such part thereof as defendant is advised it is material or necessary to make answer unto, says:

1. Defendant answering says that it is not informed, save by said bill of complaint, as to whether the complainant, Thomson Electric Welding Company, is a corporation duly organized and existing under the laws of the State of Massachusetts, having a principal place of business at Lynn, in said State, or whether the complainant, Universal Electric Welding Company, is a corporation duly organized and existing under the laws of the state of New York, having a principal place of business in the Borough of Queens, in the City and State of New York, as alleged in the said Bill of Complaint, and therefore denies the same, but defendant, United States Metal Products Company, admits that it is a corporation duly organized and existing under the laws of the State of Massachusetts and having a regular and established place of business at College Point, in the Eastern District of New York.

2. Defendant answering, upon information and belief, denies that heretofore and prior to the 24th day of February, 1905, one Adolph F. Rietzel was the true, original and first inventor or discoverer of the alleged new and useful improvements in Uniting the Component Parts of Metal Structures, or electric spot or point welding, as set forth in said bill of complaint, or any material or substantial part thereof, and denies that said alleged invention or improvement was not known or used in this country before his alleged invention or discovery thereof, and not patented or described in any printed publication in this or in any foreign country before the alleged invention or discovery thereof by said Adolph F. Rietzel, and denies that the said alleged invention was not in public use or on sale in the United States for more than two years prior to his application for Letters

Patent therefor or that the same had not been patented or caused to be patented by him or his legal representatives or assigns in any foreign country upon an application for foreign patent filed more than twelve months prior to the filing of his application for Letters Patent of the United States thereof, and were not, nor had not been abandoned.

3. Defendant, further answering, says that it has no knowledge, save as derived from the bill of complaint herein, as to whether the said Adolph F. Rietzel, by an instrument in writing alleged to have been executed, delivered and recorded in the Patent Office, sold, assigned or transferred unto the Thomson Electric Welding Company, a corporation of Maine, all of his alleged right, title or interest in and to the said application for Letters Patent, or in and to the alleged invention or improvement therein described, or as to whether the said alleged instrument in writing authorized or requested the Commissioner of Patents to grant unto the said Thomson Electric Welding Company, of Maine, any Letters Patent which might be issued pursuant to said application, and therefore leaves complainant to make such proof thereof as it may be advised.

4. Defendant, further answering, upon information and belief, admits that Letters Patent of the United States, No. 928,701, were issued to Thomson Electric Welding Company, a corporation of Maine, on the 20th day of July, 1909, but whether or not the said Letters Patent were signed, sealed, executed or issued in due form of law in all respects, or whether the provisions of the statutes of the United States in such case made and provided were only or at all complied with, this defendant has no knowledge, and therefore leaves complainant to make such proof thereof as it may; but this defendant denies that there was any valid grant unto the said Thomson Electric Welding Company, of Maine, its successors or assigns for the term of seventeen years from the date of said Letters Patent of the alleged full and exclusive right of making, using or vending to others to be used the said alleged improvements.

5. This defendant is not informed, save by the bill of complaint, as to whether the several instruments in writing set forth in said bill of complaint as assigning and transferring to these complainants or any of them the rights and interests alleged in the bill of complaint as arising out of the said Letters Patent, No. 928,701, were ever made, executed or recorded in the Patent Office of the United States as alleged, and therefore, upon information and belief, denies the same and leaves the complainants to make such proof thereof as they may be advised is material.

6. This defendant, further answering, says that it has no knowledge, information or belief that the said Letters Patent No. 928,701 is for the art of electric spot or point welding; or that spot or point welding is covered by the claims of the aforesaid Letters Patent, or that it is of great value and importance or that complainants have expended large sums of money in exploiting the aforesaid alleged invention of said Letters Patent, or whether or not complaiannts

have spent large or any sums of money in bringing said alleged invention to the notice of the various manufacturing concerns, or whether complainants have been paid large or any sums of money for the privilege of using the alleged invention covered by the claims of said patent, or as to whether or not complainants have received large or any sums of money for rights to use said invention or expect to receive further large or any sums of money for such rights, and therefore denies the same.

7. Defendant, further answering, upon information and belief, denies that it has had any knowledge of the premises set forth in the bill of complaint, or of the alleged exclusive rights or privileges of the complainants herein, or without the alleged license or permission of said complainants, or against their will and restraint, or in violation or infringement of their alleged rights under said Letters Patent, since the issuance thereof, or within six years prior to the filing of the bill of complaint herein, or at any other time, unlawfully or wrongfully made, used or sold within the Eastern District of New York, and at its factory in College Point, in said District, or elsewhere within the United States, or now continues or threatens to continue to make, use or sell in said District any metal plates, articles or metal work embodying, containing or employing the alleged invention of said Letters Patent or any substantial or material parts thereof in alleged violation of complainant's rights.

8. Defendant, further answering, upon information and belief, says that it is not informed, save as alleged in the bill of complaint herein, as to whether the allegations set forth in paragraph 10 of said bill of complaint are true and correct, and therefore denies the same and leaves complainants to make such proof thereof as they may be advised.

9. This defendant, further answering, on information and belief, avers that the said Adolph F. Rietzel, for the purpose of deceiving the public, made the descriptions and specifications filed by him in the Patent Office as a part of his application for said Letters Patent No. 928,701, to contain less than the whole truth relative to his alleged invention or discovery, and that the said Letters Patent No. 928,701 are therefore invalid and void.

10. This defendant, further answering, says that the alleged invention described in said Letters Patent No. 928,701 was not, at the date of the application for said Letters Patent, a proper subject of Letters Patent of the United States, and did not involve, constitute or amount to invention or discovery, but was in fact the mere adoption of the inventions or discoveries of others, made, used, patented and described in printed publications long prior to the application for said Letters Patent, and prior to the said alleged invention of said Adolph F. Rietzel.

11. This defendant, further answering, on information and belief, denies that the said Adolph F. Rietzel was the original and first inventor or discoverer of the improvements described and claimed in said Letters Patent No. 928,701 or of any material or substantial

parts thereof and that the said alleged inventions, and improvements had been prior to the said alleged invention and discovery thereof by the said Adolph F. Rietzel, patented, described and shown in the following United States Letters Patent and had been known and used by the patentees thereof as follows, to wit:—

And other United States and foreign Letters Patent at present to the defendant unknown, which defendant prays leave when discovered to insert herein by amendment.

12. This defendant, further answering, on information and belief, avers that the said Adolph F. Rietzel was not the original or first inventor or discoverer of the alleged inventions of Letters Patent No. 928,701 or of any material or substantial part thereof, but that the same and all material or substantial parts thereof was known and in public use and the products or articles claimed therein were on sale in this country prior to the date of said Rietzel's application for said Letters Patent No. 928,701 by the following named persons whose places of residence are given, together with the places where such public use or sale occurred:

Edwin E. Angell, of Somerville, Mass., at Somerville, Mass., and elsewhere in the United States;

George D. Burton, of Somerville, Mass., at Somerville, Mass., and elsewhere in the United States;

Robert P. Brown, of New York City, N. Y., at New York City, N. Y., and elsewhere in the United States;

Herman G. Blevin, of Newcastle, Penn., at Newcastle, Penn., and elsewhere in the United States;

Charles L. Coffin, of Detroit, Mich., at Detroit, Mich., and elsewhere in the United States.

Eugene Diven, of Elmira, N. Y., at Elmira, N. Y., and elsewhere in the United States;

Thomas A. Edison, of Orange, N. J., at Orange, N. J., and elsewhere in the United States;

Richard Eyre, of Johnstown, Pa., at Johnstown, Pa., and elsewhere in the United States;

Rudolph M. Hunter, of Philadelphia, Pa., at Philadelphia, pa., and elsewhere in the United States;

Henry F. A. Kleinschmidt of Johnstown, Pa., at Johnstown, Pa., and elsewhere in the United States;

Lorain Steel Co., Lorain, Ohio, at Lorain, Ohio, and elsewhere in the United States;
Arthur J. Moxham, of Johnstown, Pa., at Johnstown, Pa., and elsewhere in the United States;
Franklin E. Morse, New York City, N. Y., at New York City, N. Y., and elsewhere in the United States;
David W. Payne, Elmira, N. Y., at Elmira, N. Y., and elsewhere in the United States;
John C. Perry, of Clinton, Mass., at Clinton, Mass., and elsewhere in the United States;
Russell Robb, of Boston, Mass., at Boston, Mass., and elsewhere in the United States;

Elihu Thomson, of Lynn, Mass., at Lynn, Mass., and elsewhere in the United States;
Henry C. White, Worcester, Mass., at Worcester, Mass., and elsewhere in the United States.

And by others at present to this defendant unknown, the names and addresses of whom and the places where the said uses and sale occurred by defendant, when discovered, prays leave to insert herein by amendment.

13. This defendant further answering on information and belief avers that the methods claimed in said Letters Patent No. 928,701 are merely an adaptation of old and known methods to accomplish no novel result, and consists in the omission of a step or steps of said old and known methods with the omission in said claims of a statement of the purpose or result accomplished by said steps.

14. This defendant further answering on information and belief alleges that the said Letters Patent No. 928,701 are invalid by reason of the fact that the claims thereof are too broad in view of the state of the prior art at the time that the application for such Letters Patent was filed, and also by reason of the fact that said claims were so greatly expanded beyond what they were when the Rietzel application was originally filed, as to describe a different invention.

15. Defendant further answering on information and belief alleges that if any invention is involved in the claims in suit of the Rietzel patent No. 928,701, that then, and in that event, the said Rietzel patent was surreptitiously and unjustly obtained for that which was in fact invented by one Johann Harmatta, of Szepesvaralja, Hungary, who was using reasonable diligence in adapting and perfecting the same.

16. This defendant further answering denies all and all manner of wrongdoing wherewith it is charged in the bill of complaint, asserts that the said patent No. 928,701 has never been adjudicated in the courts, and denies the rights of complainants to an

injunction or an accounting, or any other relief prayed for in said bill or otherwise, and defendant prays the same effect for this answer as if it had pleaded the several matters and those aforesaid, as if for the reasons thereof it had demurred to the said bill of complaint where a demurrer would have been proper, and the same benefit thereof as if it had specially pleaded to the bill where a special plea would have been proper, and defendant submits to this Honorable Court and insists that the premises considered the complainants have no right to any further answer to said bill or any part thereof than is hereinbefore contained, and no right to any discovery, injunction, accounting, or any relief prayed for in said bill, and this defendant prays to be hence dismissed with its reasonable costs and charges in this behalf most wrongfully sustained.

THOMSON ELECTRIC WELDING COMPANY and UNIVERSAL ELECTRIC WELDING COMPANY, PLAINTIFFS,

vs.

UNITED STATES METAL PRODUCTS COMPANY, DEFENDANT.

IN EQUITY No. 11.

REPLICATION.

The replication of the above-named plaintiffs to the answer of the above-named defendant.

These replicants, saving and reserving to themselves all and all matter of advantage or exception which may be had and taken to the manifold errors, uncertainties, and insufficiencies of the answer of said defendant, for replication thereunto say that they do and will ever maintain and prove their said bill to be true, certain, and sufficient in the law to be answered unto by said defendant, and that the answer of said defendant is very uncertain, evasive, and insufficient in the law to be replied unto by these replicants; without this, that any other matter or thing in the said answer contained material or effectual in the law to be replied unto, confessed, or avoided, traversed, or denied, is true; all which matters and things these replicants are ready to aver, maintain, and prove as this Honorable Court shall direct, and humbly as in and by their said bill they have already prayed.

No. 523,766 of E. Thomson "

and is also the owner of other inventions, U. S. Patents, and applications for U. S. Patents pertaining to the welding of metal plates over their plane surfaces by electricity, the union being affected in spots by the passage of the current from plate to plate, including machines and processes used in said electric welding, and the product of said processes; and

WHEREAS the Thomson Electric Welding Co., a corporation organized and existing under the laws of the State of Maine, the predecessor of the Thomson Co., party of the first part hereto, entered into agreements with the Standard Pulley Mfg. Co., a corporation organized and existing under the laws of the State of New York, respectively dated March 15, 1905, Nov. 3, 1905, and Nov. 27, 1905, by which the said Standard Pulley Mfg. Co. ac-

quired certain rights under the inventions, patents, and applications for patents of the predecessor of the Thomson Company; and

WHEREAS, by an agreement dated Feb. 24, 1906, the said Standard Pulley Mfg. Co. sold, assigned and transferred to the American Co., the party of the second part hereto, the full and exclusive rights acquired by it under the said agreements with the predecessor of the Thomson Co., respectively dated March 15, 1905, November 3, 1905 and November 27, 1905, so far as the same relate to metal cooking utensils, metal hollow and table ware, metal house ware, metal cans, and articles of a similar character, or to electric welding machines or parts thereof, to be used in the manufacture of such ware and articles, together with other rights set forth in said agreement of February 24, 1906; and

WHEREAS the predecessor of the Thomson Co., the American Co., and the said Standard Pulley Mfg. Co. entered into an agreement on March 14, 1906, wherein the predecessor of the Thomson Co. consented to and ratified the said assignment and transfer of February 24, 1906, from the said Standard Pulley Mfg. Co. to the party of the second part hereto; and

WHEREAS by an agreement dated March 20, 1906, the predecessor of the Thomson Co., party of the first part, pursuant to the provisions of the said agreement of March 14, 1906, granted to the American Co., party of the second part hereto, a certain lease or license under the inventions, United States patents, and applications for U. S. Letters Patent of said predecessor of the Thomson Company; and whereas said lease or license of March 20, 1906, was thereafter modified by agreements in writing between the predecessor of the Thomson Co. and the American Co., dated respectively September , 1906 and April 11, 1908; and

WHEREAS the parties hereto desire to modify the said Lease and License in certain respects:

NOW, THEREFORE, FOR AND IN CONSIDERATION OF THE sum of One Dollar ($1.00) by each to the other in hand paid, the receipt of which is hereby acknowledged, and in consideration of the premises, it is hereby agreed between the parties to these presents as follows:

First: The Thomson Co. hereby gives and grants unto the American Co., the exclusive right to use and to license others to use, the machines and processes described and covered in and by the above recited patents and applications for patents, or in and by any other U. S. Letters Patent that is now or may be hereafter acquired by the Thomson Co., pertaining to the welding of metal plates over their plane surfaces by electricity, the union being effected in spots by the passage of the current from plate to plate in the manufacture of metal cooking utensiles, metal hollow and table ware, metal house ware, metal cans, and articles of a similar character, whether tinned, galvanized or japanned, or finished in any other manner; also the exclusive right to make, use and sell, and to license others to make, use and sell, metal cooking utensiles, metal hollow and

table ware, metal house ware, metal cans, and articles of a similar character embodying the inventions, or any of them described and covered in and by the above recited patents and applications for patents, or any other patents that are now owned, or may be hereafter acquired by the Thomson Co., pertaining to the welding of metal plates over their metal surfaces by electricity, the union being effected in spots by the passage of the current from plate to plate, or to the articles produced by any such process, it being understood that the machines for manufacturing such ware shall be obtained and leased from the Thomson Co. under the terms and provisions of this agreement except as hereinafter provided.

Second: The Thomson Co. in consideration of one dollar ($1.00) to it paid by the American Co., the receipt whereof is hereby acknowledged, and of the covenants of the American Co. hereinafter contained, does hereby lease and let to the American Co. (subject, however, to the terms, and conditions of this lease), the machines heretofore furnished by the Thomson Co. or its predecessor, to the American Co. under the previous contracts above mentioned, and the machines to be hereafter furnished by the Thomson Co. to the American Co. pursuant to the terms of this lease; and this lease shall continue in force until the expiration of all the Letters Patent of the United States, both of the Thomson Co. and of the American Co., and of L. S. Lachman, of the City of New York, also of Maurice Lachman of the City of New York, whether owned or controlled by any or all of the said parties, the inventions of which are or shall be embodied in said machines, or at any time involved in the use thereof, or embodied in the product thereof, unless this lease shall be sooner terminated by the fault of the American Co. in accordance with the provisions hereinafter contained; whereupon the possession of such machines shall immediately revest in and be restored to the Thomson Co.

Third: The American Co. shall purchase all of the welding machines used by it, or its sub-lessees under this license, from the Thomson Co., except as hereinafter provided, and the Thomson Co. agrees to supply said machines as soon as possible upon request, and when supplied, said machines shall be subject to all the conditions and covenants of this lease.

Fourth: As soon as any such machine has been delivered by the Thomson Co. to the American Co., or its sub-lessee, the American Co. shall pay to the Thomson Co. for the said machine an amount equal to the cost to the Thomson Co. to produce the machine in question, plus 15%, using every reasonable effort to produce such machine at the lowest possible cost to it. The American Co. shall also pay to the Thomson Co. on each such hand machine an annual rental or royalty of One Hundred Dollars ($100.00), and on each semi-automatic machine an annual rental or royalty of One Hundred Twenty-Five Dollars ($125.00), and on each automatic machine an annual rental or royalty of One Hundred Fifty Dollars ($150.00), the said annual rental to be paid to the Thomson Co. in quarterly installments, in January, April, July and October of each

and every year during the continuance of this lease. The first quarterly payment on each such machine shall be computed pro rata from the date of its delivery by the Thomson Co. to the beginning of the following quarterly period.

Fifth: Said machines are leased only for the purpose of welding according to the method heretofore described, and for the purpose of welding articles heretofore described, and the American Co. agrees not to use, nor to permit others to use, said machines in any other way or for any other purpose.

Sixth: Said machines may be used by the American Co. in any locality in the United States, and the American Co. may sub-lease and let any and all of said machines to any party or parties within the United States it deems fit, but said machines shall, nevertheless, be subject to all the conditions and covenants of this lease when sub-leased and let, the same as if they were used by the American Co. itself.

Seventh: The American Co. shall not add to, or subtract from, said welding machines, any mechanism whatever now or hereafter organized or connected therewith by the Thomson Co., nor allow to be made any change or alteration in same, without the consent and authority in writing of the Thomson Co.; the Thomson Co. and its agents may at all reasonable times have convenient access to said machines to examine and inspect the same and the use thereof, and to alter or improve the same, as herein contemplated, as it shall see fit.

Eighth: The American Co. covenants and agrees never at any time during the terms of the said Letters Patent above referred to, or any of them, to violate or infringe said patents under which the American Co. is hereby licensed, or any of them nor ever to contest or question the validity of the same, or the sufficiency of their specifications, or the Thomson Co.'s title thereto.

Ninth: It is also agreed that the American Co. shall at any time have the right, upon six months' notice in writing of its intention so to do, to surrender any machine, and, upon the surrender of such machine and the payment to the Thomson Co. of all sums due as original payment and continuing rental or royalty to the day of the expiration of the said notice, said machine shall be released from this instrument, and the American Co. shall not be required to pay any further continuing rental or royalty upon any machine so surrendered; on the surrender of all the machines subject to this instrument, the American Co. not being in default in any of its provisions, this lease shall be cancelled, and all the further obligations of the parties hereto cease and determine.

Tenth: It is further agreed that, if the American Co. shall have fully complied with the terms and conditions herein set forth, and not otherwise, then upon the expiration of all the Letters Patent of the United States, owned or controlled by both the Thomson Co. and the American Co., and by said L. S. Lachman and said Maurice Lachman, the inventions of which shall at any time be embodied

in said machines or involved in the use thereof, the American Co. shall have the privilege of purchasing said machines upon the payment therefor of One Dollar ($1.00), and upon such purchase the Thomson Co. will transfer the property in said machines to said American Co. by a proper bill of sale.

Eleventh: In case the American Co. neglects or refuses to perform and observe any or all of the agreements, terms, or conditions in this lease contained, the Thomson Co. shall have the right to terminate the same by giving to the American Co. fifteen days' notice in writing of its intention so to do, and if the American Co. fails to repair and make good such default or defaults, on account of which the notice was given, on or before the expiration of said fifteen days, this lease, and all the rights of the American Co. hereunder, shall be wholly at an end, and the Thomson Co. released from all its obligations herein contained, but the American Co. shall not thereby be released from the liability to pay the rentals or royalties at the rate aforesaid already accrued at the termination of the lease, nor from the American Co.'s covenant in Clause "Eighth" hereof. Upon the termination of this lease in any of the contingencies aforesaid, said machines shall be released and discharged from this lease, and the possession thereof shall immediately revest in and be restored to the Thomson Co. who, by itself or its agents, may enter the premises of the American Co. or the sub-lessee, and all persons claiming under it, and may take or remove the machines without being deemed guilty of any trespass or tort; or the Thomson Co. may pursue the appropriate remedy at law or in equity against the American Co., any sub-lessee, or the persons in whom the machines, or any parts thereof, may be found. And on the termination of the said lease upon either or any of the events or contingencies aforesaid, the American Co. shall have no claim or right to the repayment by the Thomson Co. of the whole or any part of the sums which the American Co. may have paid as an original payment, or as royalties or otherwise, under this agreement, or as consideration for the execution of the same.

Twelfth: In case any of the said machines be subleased by the American Co. by an instrument in writing, which shall reserve practically similar security to the American Co., in relation to such machine or machines, as is reserved to the Thomson Co. by this agreement, and such sub-lessee shall neglect or refuse to perform and observe any of the provisions, terms or conditions in said sub-lease to it contained in relation to any machine so sub-let, or the sub-lessee shall fail to repair and make good such default within fifteen (15) days after written notice thereof is given to the American Co. by the Thomson Co., then in every such event the provisions of the preceding article of this agreement (Article No. Eleventh) are not to be operative or apply, provided, however, that the American Co. shall promptly thereafter exercise its right to terminate the sub-lease and use every reasonable effort, by way of legal proceedings or otherwise, and shall spare no reasonable ex-

pense, to recover the possession of the machine or machines so held under such sub-lease.

Thirteenth: It is agreed by the American Co. that it will do everything reasonably within its power to persuade its sub-lessees under this agreement to use welding machines furnished by the Thomson Co. in the manufacture of the ware heretofore specified. But it is agreed between the parties hereto that if any party is now using electric welding machines in the manufacture of the above specified ware, which machines were not obtained from the Thomson Co., or its predecessor, the American Co. shall have the right to license the said party to use the said machines under the patents and applications for patents hereinbefore referred to, for the purpose of manufacturing the kinds of ware above specified, and to use and sell the ware so manufactured, provided that the American Co. shall pay to the Thomson Co. an annual rental or royalty of one hundred dollars ($100.00) on each hand machine, and an annual rental or royalty of One Hundred Twenty-Five Dollars ($125.00) on each semi-automatic machine, and an annual rental or royalty of One Hundred Fifty Dollars ($150.00) on each automatic machine, so licensed, as specified in the Clause "Fourth" hereof, so long as such license remains in force; which payments said American Co. agrees to make.

Fourteenth: All the rights, interests and remedies vested in the Thomson Co. under this instrument, and also all those which belong to it by reason of ownership of said machines now or hereafter embraced in or made subject to the terms of this agreement, shall be deemed to belong to and be enforcible by the successors and assigns of the Thomson Co., and in their own name respectively.

IN WITNESS WHEREOF the parties hereto have caused their names to be signed hereto, and their corporate seals to be affixed by their proper officers, thereunto duly authorized, the day and year first above written.

(N. E. F.)

DEFENDANT'S EXHIBIT AGREEMENT OF JUNE 10, 1914, BETWEEN THOMSON ELEC. WELDING CO, AND AMERICAN ELEC. WELD. CO.

AGREEMENT.

This agreement made in triplicate this (tenth) day of (June), 1914, by and between the Thomson Electric Welding Company, a corporation organized and existing under the laws of the State of Mass., and having its principal place of business at Lynn, in the Commonwealth of Massachusetts, hereinafter called *Thomson Company*, and the American Electric Welding Company, a corporation organized and existing under the laws of the State of New York, hereinafter called *American Company*, parties of the first part, and the National Enameling & Stamping Co., a corporation organized and existing under the laws of the State of New Jersey, and carrying on business in the City, County and State of New York, hereinafter called *National Company*, party of the second part. Witnesseth:

Whereas Thomson Company and American Company entered into an agreement on August 3, 1912 whereby American Company obtained a certain exclusive license from Thomson Company under all the patents of the United States that it then owned or might thereafter acquire pertaining to the welding of metal plates over their plane surfaces by electricity, the union being effected in spots by the passage of the current from plate to plate, or to articles produced by such process, to use and to license others to use the machines and processes of said patents in the manufacture of metal cooking utensils, metal hollow and table ware, metal house ware, metal cans and articles of similar character, whether tinned, galvanized or japanned, or finished in any other manner, and to make, use and sell and to license to others to make, use and sell metal cooking utensils, metal hollow and table ware, metal house ware, metal cans and articles of a similar character embodying the inventions, or any of them, described and covered in and by said patents; and

Whereas National Company and Eisenhutte Silesia Aktien Gesselschaft, a corporation organized and existing under the laws of Germany, hereinafter called Silesia Company, entered into an agreement on the 31st day of December, 1904, by which agreement National Company was to obtain from Silesia Company certain rights with relation to an invention of Johann Harmatta for which an application for Letters Patent of the United States had been filed on December 3, 1903, Serial No. 183,677, upon which application Letters Patent of the United States No. 1,046,066 were granted on December 3, 1912 to Thomson Company as assignee of said Harmatta; and

Whereas Thomson Company and Silesia Company entered into an agreement on April 3rd, 1912 whereby Silesia Company, representing that it owned or controlled the said Harmatta application, agreed to cause the same to be assigned to the Thomson Company and also to assign to Thomson Company all its rights under its said agreement with National Company; and

Whereas Thomson Company and American Company have heretofore asserted and now assert that the said agreement between National Company and Silesia Company is null and void, whereas National Company has asserted that said agreement is good and valid; and

Whereas it is the desire of Thomson Company and American Company that American Company acquire all rights, if any, that National Company may have in and under said Harmatta patent, including all rights it may have to sue and recover for past infringement of said Harmatta patent and National Company desires to obtain a certain release and license under this and other patents as hereinafter more particularly specified.

Now, Therefore, for and in consideration of the premises and in further consideration of the mutual benefits and advantages accruing to the parties hereto by reason of the covenants and conditions of this agreement, it is mutually agreed as follows:

1. The aforesaid agreement between the National Company and Silesia Company is hereby cancelled by mutual consent and the same shall be without force and effect hereafter for any purpose and all rights that National Company may have had under said agreement, including the right to sue for and recover profits and damages or other recoveries from any infringers of said Harmatta Patent, are hereby assigned and transferred and set over to American Company and its successors and assigns.

2. Thomson Company and American Company hereby grant and each of them hereby grants to National Company a full and complete release from any claim that they or either of them may have against National Company for the infringement of any letters patent of the United States pertaining to the welding of metal plates over their plane surfaces by electricity, the union being effected in spots by the passage of the current from plate to plate, or against the customers of National Company by reason of their use or sale of articles obtained from National Company, and the said Thomson Company and American Company hereby grant and each of them hereby grants to the National Company a full and complete release from any and all claims, demands and causes of action arising out of, or which but for the covenants herein contained might at any time hereafter accrue under, the aforesaid contract between Silesia Company and National Company in favor of Silesia Company, its successors and assigns, against National Company.

3. American Company and Thomson Company, and each of them, hereby grants to and confers upon National Company, and its successors in business, a non-transferable license, under all pat-

ents pertaining to the welding of metal plates over their plane surfaces by electricity, the union being effected in spots by the passage of the current from plate to plate, owned or controlled in whole or in part by Thomson Company and American Company, both or either of them, or under which American Company, is licensed, including all patents referred to in the aforesaid agreement between Thomson Company and American Company, dated August 3, 1912, and under all other patents relating to the aforesaid art heretofore or hereafter acquired or controlled by them or either of them in whole or in part, including all patents for improvements on the inventions covered by any of the patents hereinbefore referred to, to use any patented machines, including those which the National Company now has in use, covered by such patents or any of them, and to use any patented process or processes covered by the said patents or any of them, in the several factories of National Company, including any factories hereafter acquired by it, in the manufacture of its metal cooking utensils, metal hollow and table ware, metal house ware, metal cans and articles of a similar character whether tinned, galvanized or japanned, or finished in any other manner, and to make or have made for it said patented machines for said use, and to make, use and sell said utensils, wares, cans and articles, the license hereby granted to and conferred upon National Company to continue to the full end of the term of all the patents hereinbefore referred to under which this license is granted, and of any extensions thereof.

4. And said Thomson Company and American Company hereby grant and each of them hereby grants to and confers upon National Company, a non-transferable license under the aforesaid Harmatta patent for the full term of said patent or any extensions thereof, to make, use or have made for it any machine covered by said patent, and to use the process covered thereby in the several factories of National Company, including those that may be hereafter acquired by it, for the manufacture of any products whatsoever of National Company, and to make, use and sell said products. The aforesaid license from Thomson Company for the manufacture and sale by National Company under the Harmatta patent of any products other than metal cooking utensils, metal hollow and table ware, metal house ware, metal cans and articles of a similar nature, whether tinned, galvanized or japanned, or finished in any other manner, is, however, subject to the rights heretofore granted by Thomson Company to the Universal Electric Welding Company.

5. No royalty shall be paid by National Company to Thomson Company and American Company or to either of them, or to the respective successors or assigns of either of them, for or in consideration of the license hereby granted; nor shall National Company be required to pay to said Thomson Company and American Company, or to either of them, or to the successors or assigns of either of them, any consideration whatsoever other than that speci-

fied in the first paragraph hereof, for any right, license or benefit granted to, conferred upon or acquired by National Company hereunder.

IN WITNESS WHEREOF, the parties hereto have duly executed this instrument by the hands of their respective offices, thereunto duly authorized, and have caused their respective corporate seals to be attached thereto.

May 7,1918.

Feb. 28, 1917.

Mr. J. H. Garvell,
American Chemical Paint Co.,
Philadelphia, Pa.

My dear Sir:

The committee of which I have the honor of being Chairman has accumulated some very important legal opinions regarding the validity of the Harmatta spot welding patent.

The committee has in its possession an original spot welder used in 1901, and also affidavits of a number who have worked and used the machine, saying nothing of a large volume of important matters bearing on the subject, - all of which is open to the inspection of those users of electric welding machines that come to contribute to the further work now in progress.

One of our members, Mr. Robert A. Brannigan, Manager of Patent Department, National Automobile Chamber of Commerce has given in your name, with the remarks that he understands that you have in your possession valuable information in connection with the spot welding patents. The writer will be very glad, indeed, to exchange information, and sincerely hopes that you may write him, outlining your position in the matter.

Under this cover I am handing you the form letter which we are sending out, together with application blank for contribution, and an extract from the minutes of our meeting on the 21st.

Very respectfully yours,

Chairman.

Gentlemen:-

I have your letter of February 28th and in reply beg to advise that Mr. R. S. Carrick a representative of Mr. Lee of Chicago, who was present at the Canton Meeting, called on me the day before yesterday.

I explained to Mr. Carrick in great length my position in the matter and what I thought would be necessary to win a suit. Mr. Carrick will transmit my ideas in person to Mr. Lee in Chicago, who will in turn take the matter up with you.

Thanking you for keeping me posted in these matters, I beg to remain

Very respectfully yours,

Gentlemen :-

Believing it is well to help along the cause we have filled in the subscription blank for $250.00 representing as we understand it one share of stock and the balance in bonds, and are enclosing our check for $10.00 being 10% of the subscribed stock.

We understand the balance of the stock is to be paid for on request of the Board of Directors and that the bond will be paid for at the time of the tender of said bond.

Very truly yours,

American Chemical Paint Co.

Gentlemen: Attention Mr. H. Schuerruff

I am in receipt of your favor of the 1st instant, enclosing subscription in the amount of $250.00 to the Federal Machine & Welder Company, together with check for $10.00.

As there seems to be some question over the status of your Mr. Gravell with reference to the spot welder controversy, and as to whether your company is a bona fide owner and user of welding machines, it has been decided not to accept your subscription, at least until this matter can be cleared up.

I, therefore, return your subscription blank and check.

Yours very truly.

Dominion of Canada.

PATENT OFFICE.

Certified to be a true and correct copy of original Application for Patent number 108990, filed December 1st, 1908, by Johann Harmatta, for "Electric Welding."

In Witness the seal of the Patent Office hereto affixed at the City of Ottawa in the Dominion of Canada this 28th day of April in the year of our Lord one thousand nine hundred and nineteen.

for Deputy Minister of Patents

Serial No. 108,990. Filed Dec. 1, 1903. Subject: Electric Welding. Case 1. Inventor, Johann Harmatta. 1st Report, 1241-14-4-04. 2nd Report, 1430-25-2-05. 3rd Report, 7 Jan. 11, 1906. 4th Report, 316, 26/xl., 1906. Abandoned, Nov. 30, 1907.

F. D. WITHROW,
Examiner.

CASE I.

Patent Office, Canada, Dec. 1, 1903.

APPLICATION FOR CANADIAN PATENT.

Petition with Power of Attorney.

To the Commissioner of Patents,
Ottawa.

The petition of Johann Harmatta, Engineer, a subject of the King of Hungary, residing at Szepesváralja, in the Kingdom of Hungary, showeth:

That he has invented new and useful "Improvements in Electric Welding," not known or used by others before his invention thereof, and not being in public use or on sale, with his consent or allowance as such inventor for more than one year previous to his application for a patent therefor, in Canada.

Your petitioner, therefore, prays that a patent may be granted to him for the said invention, as set forth in the specification in duplicate relating thereto, and for the purpose of the Patent Act, your petitioner elects his domicile in the City of Montreal, Province of Quebec.

Your petitioner hereby appoints Messrs. Marion & Marion, of Montreal, Province of Quebec, his attorneys with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to sign the drawings, to receive the patent, and to transact all business in the Patent Office connected therewith.

Signed at Budapest, this 5th day of November, 1903.

JOHANN HARMATTA.

Witnesses:
DR. ALEXANDER KAUFFMANEY.
CARL BEIKER.

DECLARATION.

I, Johann Harmatta, Engineer, a subject of the King of Hungary, residing at Szepesváralja in the Kingdom of Hungary, declare and say that I verily believe that I am the inventor of the new and useful "Improvements in Electric Welding," described

and claimed in the specification relating thereto and for which I solicit a patent by my petition dated fifth day of November, 1903, and I further say that the same has not been patented to me, or to others with my knowledge or consent in any country, and I further say that the several allegations contained in the said petition are respectively true and correct.

JOHANN HARMATTA.

Declared before me at Budapest, this 5th day of November, 1903.

J. DRULET,
His Britannic Majesty's Consul,
Budapest.

Stamp.

SPECIFICATION.

E. M. D., M. F. S.

To All Whom It May Concern:

Be it known that I, JOHANN HARMATTA, Engineer, a Subject of the King of Hungary, residing at Szepesváralja, in the Kingdom of Hungary, have invented new and useful "IMPROVEMENTS IN PROCESSES OF ELECTRIC WELDING" and I do hereby declare that the following is a full, clear and exact description of the same.

The subject of my invention is a process of welding thin sheet metal by means of electricity.

As is well known it is impossible, by means of the ordinary methods of electric welding, to produce a really sound seam between very thin metal sheets, from about two millimeters in thickness downward, that is to say, a seam which is perfect at every part, without there being any fusing or burning away of the material being welded.
